IMPORTANT

In correspondence concerning this instrument, please quote the type number and serial number as given on the type plate.

NOTE : The design of this instrument is subject to continuous development and improvement.
Consequently, this instrument may incorporate minor changes in detail from the information contained in this manual.

1.0 SAFETY INSTRUCTIONS

Read these pages carefully before installation and use of the instrument.

1.1 INTRODUCTION

The following clauses contain information, cautions and warnings which must be followed to ensure safe operation and to retain the instrument in a safe condition.
Adjustment, maintenance and repair of the instrument shall be carried out only by qualified personnel.

1.2 SAFETY PRECAUTIONS

For the correct and safe use of this instrument it is essential that both operating and servicing personnel follow generally-accepted safety procedures in addition to the safety precautions specified in this manual.
Specific warning and caution statements, where they apply, will be found throughout the manual.
Where necessary, the warning and caution statements and/or symbols are marked on the apparatus.

1.3 CAUTION AND WARNING STATEMENTS

CAUTION: Is used to indicate correct operating or maintenance procedures in order to prevent damage to or destruction of the equipment or other property.

WARNING: Calls attention to a potential danger that requires correct procedures or practices in order to prevent personal injury.

1.4 SYMBOLS

High voltage ≥ 1000 V (red)

Live part (black/yellow)

Read the operating instructions

Protective earth (grounding) terminal (black)

1.5 IMPAIRED SAFETY PROTECTION

Whenever it is likely that safety-protection has been impaired, the instrument must be made inoperative and be secured against any unintended operation. The matter should then be referred to qualified technicians.
Safety protection is likely to be impaired if, for example, the instrument fails to perform the intended measurements or shows visible damage.

1.6 GENERAL CLAUSES

1.6.1 WARNING: The opening of covers or removal of parts, except those to which access can be gained by hand, is likely to expose live parts and accessible terminals which can be dangerous to live.

1.6.2 The instrument shall be disconnected from all voltage sources before it is opened.

1.6.3 Bear in mind that capacitors inside the instrument can hold their charge even if the instrument has been separated from all voltage sources.

1.6.4 WARNING: Any interruption of the protective earth conductor inside or outside the instrument, or disconnection of the protective earth terminal, is likely to make the instrument dangerous.
Intentional interruption is prohibited.

1.6.5 Components which are important for the safety of the instrument may only be renewed by components obtained through your local PHILIPS organisation. (See also chapter 12).

1.6.6 After repair and maintenance in the primary circuit, safety inspection and tests, as mentioned in chapter 14 have to be performed.

2.0 INTRODUCTION

This compact dual channel digital storage oscilloscope features an extensive sampling rate of 500 Megasamples/s with a vertical bandwidth of 300 MHz and a vertical resolution of 10 bit. An outstanding feature is the AUTO-SET pushbutton facility, which automatically sets various controls of the instrument to suit the input signal value. In this way, optimum ease of operation is obtained as the input signal immediately presents a correct, stable display on the bright C.R.T. screen.
The brightness is independent of the time base settings.
The M68000 microprocessor gives a wide choise of measurement and display possibilities, which can be selected via the ergonomic designed front panel.

Figure 2.1 500 Megasamples/s digital storage oscilloscope.

The oscilloscope is provided with integrated circuits (including thinfilm circuits), which guarantee highly-stable operation.

Furthermore, connection to the local mains is simplified by a tapless switched-mode power supply that covers most voltage ranges in use: 90 V...264 V a.c.

All these features make this oscilloscope suitable for a wide range of measuring applications.

A. General

This instrument has been designed and tested in accordance with IEC publication 348 for Class I instruments.
This specification is valid after the instrument has warmed up for 30 minutes.

Properties expressed in numerical values with tolerances stated, are guaranteed by the manufacturer.
Numerical values without tolerances are typical and represent the characteristics of an average instrument.
Within 5 minutes after switching on, the temperature difference inside the instrument has reached 70 percent of its end value.

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.1	CATHODE RAY TUBE		
3.1.1	Type	Philips D18-190GH/129	180 mm rectangular single beam tube.
3.1.2	Usefull screen area (h. x w.)	100 mm x 120 mm	For graticule see 3.1.7.
3.1.3	Screen type	GH (P31)	
3.1.4	Total acceleration voltage	16 kV	
3.1.5	Spot size	0,3 mm	Tube only.
3.1 6	Maximum trace distortion		Deviation from straight line.
	-@ screen periphery	1 mm	Outside central 80 mm (vert.) x 100 mm (hor.).
3.1.7	Graticule	Internal, fixed	
	-Illumination	Continuously variable	
	-Size (h. x w.)	80 mm x 100 mm	Centered @ 50 mm from top of CRT screen (hor.) and @ 50 mm from left edge of CRT screen (vert.).
	-Engravings		
	division lines	@ 10 mm	Horizontal and vertical.
	2 mm tick marks	@ 2 mm	On vertical and horizontal central axes.
	0.5 mm tick marks	@ 2 mm	On horizontal lines #2,3,4,6,7,8.
	dots	@ 2 mm	On dotted lines @ 1,5 div and 6,5 div from top of graticule.
	percentages	100-90-10-0 %	To facilitate rise and fall time measurements.
3.1.8	Orthogonality		Measured @ centre of screen.
		$90 \pm 0,5^{o}$	(Angle between X and Y axes, when traces are written in X- and Y direction alternately).

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.1.9	Intensity	Blank to max. intens.	Separate front panel controls for trace and text.
3.1.10	Focus	Manually set	Common screwdriver control on front for trace and text.
3.1.11	Trace rotation		Screw driver control on front; direction of screw driver rotation same as direction of trace rotation.
	-Minimum range	14^{o}	Either X or Y trace can be aligned with graticule, when environmental magnetic field is within 0,1 mT.
3.2	SIGNAL ACQUISITION		
3.2.1	Sampling type		
	-@ 100 ns/div... 360 s/div:	Real time	
	-@ 5 ns/div... 50 ns/div:	Equivalent time	Random sampling.
3.2.2	Maximum sampling rate		Sampling rate depends on time/div setting.
	-Real time:	500 megasamples/s	
	-Equivalent time:	10 gigasamples/s	Repetitive only.
	-Ext. clock	50 kilosamples/s	Max. aperture uncertainty of 10 us.
3.2.3	Vertical (=voltage) resolution	10 bits	(= 0,1 % of full range).

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.2.4	Horizontal (=time) resolution		
	-In single Ch. or added Ch. acquisition		
	@ 1 ms/div... 5 s/div	4096 samp./acquisition	1 Sample = 0,025 % of full record.
	@ 5 ns/div... 500 us/div	512 samp./acquisition	1 Sample = 0,2 % of full record.
	-In dual channel acquisition		
	@ 1 ms/div... 5 s/div	2048 samp./acquisition	1 Sample = 0,05 % of full record.
	@ 5 ns/div... 500 us/div	512 samp./acquisition	1 Sample = 0,2 % of full record.
3.2.5	Record length	10,2 x time/div	Display in unmagnified position.
3.2.6	Acquisition time		
	-Real time	10,2 x time/div	
	5 s/div ... 1 ms/div	+ 1 ms/div	} }Exclusive delay time.
	500 us/div ... 200 ns/div	+ 10 ms	} }
	-Equivalent time		
	@ 5ns/div	2 s	} After this time there is a 99 % probability of all dots being updated to the new acquisition.
	@ 100 ns/div	10 ms	
3.2.7	Sources	Channel A	} Both channels can be inverted before acquisition.
		Channel B	
3.2.8	Acquisition modes	1 channel only	Full memory available for 1 channel.
		2 channels	Simultaneously sampled; 2 channels share memory.
		Ch.A and ch.B added	Full memory available for added channels.
		Average	Combined with 1 channel only, 2 channels or ch. A and ch. B added.
		MIN / MAX	Combined with 1 channel only, 2 channels or ch. A and ch. B added.

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.1.9	Intensity	Blank to max. intens.	Separate front panel controls for trace and text.
3.1.10	Focus	Manually set	Common screwdriver control on front for trace and text.
3.1.11	Trace rotation		Screw driver control on front; direction of screw driver rotation same as direction of trace rotation.
	-Minimum range	14^{o}	Either X or Y trace can be aligned with graticule, when environmental magnetic field is within 0,1 mT.
3.2	SIGNAL ACQUISITION		
3.2.1	Sampling type		
	-@ 100 ns/div... 360 s/div:	Real time	
	-@ 5 ns/div... 50 ns/div:	Equivalent time	Random sampling.
3.2.2	Maximum sampling rate		Sampling rate depends on time/div setting.
	-Real time:	500 megasamples/s	
	-Equivalent time:	10 gigasamples/s	Repetitive only.
	-Ext. clock	50 kilosamples/s	Max. aperture uncertainty of 10 us.
3.2.3	Vertical (=voltage) resolution	10 bits	(= 0,1 % of full range).

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.2.4	Horizontal (=time) resolution		
	-In single Ch. or added Ch. acquisition		
	@ 1 ms/div... 5 s/div	4096 samp./acquisition	1 Sample = 0,025 % of full record.
	@ 5 ns/div... 500 us/div	512 samp./acquisition	1 Sample = 0,2 % of full record.
	-In dual channel acquisition		
	@ 1 ms/div... 5 s/div	2048 samp./acquisition	1 Sample = 0,05 % of full record.
	@ 5 ns/div... 500 us/div	512 samp./acquisition	1 Sample = 0,2 % of full record.
3.2.5	Record length	10,2 x time/div	Display in unmagnified position.
3.2.6	Acquisition time		
	-Real time	10,2 x time/div	
	5 s/div ... 1 ms/div	+ 1 ms/div	} Exclusive delay time.
	500 us/div ... 200 ns/div	+ 10 ms	} Exclusive delay time.
	-Equivalent time		
	@ 5ns/div	2 s	} After this time there is a 99 % probability of all dots being updated to the new acquisition.
	@ 100 ns/div	10 ms	} After this time there is a 99 % probability of all dots being updated to the new acquisition.
3.2.7	Sources	Channel A	} Both channels can be inverted before acquisition.
		Channel B	} Both channels can be inverted before acquisition.
3.2.8	Acquisition modes	1 channel only	Full memory available for 1 channel.
		2 channels	Simultaneously sampled; 2 channels share memory.
		Ch.A and ch.B added	Full memory available for added channels.
		Average	Combined with 1 channel only, 2 channels or ch. A and ch. B added.
		MIN / MAX	Combined with 1 channel only, 2 channels or ch. A and ch. B added.

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.2.9	Maximum time difference	200 ps	Two channels are sampled simultaneously.
3.3	CHANNELS A AND B		
3.3.1	Input connector	BNC with probe read-out	Probe read-out causes instrument to change V/div indication, input impedance and attenuator setting according to probe (when fitted with a probe indicator).
3.3.2	Input impedance (In high Z position)		For frequency > 1 MHz see Fig. 3.1.
	-R parallel	1 M Ohm ± 1 %	}In DC position of input coupling. In AC position of input coupling.: 18 nF in series with R par. & C par.
	-C parallel	14 pF	
			}In 0 position of input coupling: R par. = ∞.
	-Maximum input capacitance difference	1,5 pF	Capacitance difference between channel A, channel B and/or trigger input.
3.3.3	Input impedance (in 50 ohm position)		
	-R parallel	50 Ohm ± 1 %	In DC, AC and 0 position of input coupling.
3.3.4	Input coupling	a.c. d.c. 0	In 0 position: channel input disconnected from BNC and connected to ground.
3.3.5	Max. input voltage		Instrument should be properly grounded through the protective-ground conductor of the power cord.
	-In high Z position (d.c. + a.c. peak)	300 V	Up to 1 MHz; for freq. > 1 MHz see Fig. 3.2.
	-In 50 ohm position		
	d.c.	5 V	}
	a.c. (r.m.s.)	5 V	} Max. 50 mJ during any
	a.c. (peak)	50 V	} 100 ms interval.
			}

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.3.6	Deflection coefficient		Measured with a square wave signal of 2 kHz.
	-Steps	5 mV/div...5 V/div	In a 1-2-5 sequence of 10 steps.
	-Vernier ratio	1:2,7	Continuously variable between steps.
	Read out accuracy	± 15 %	
	-Error limit (Ambient:15..35°C)		Add 3 % for ambient: 0...50°C.
	overall	± 2 %	}Add 2% in 100 ns/div. }Vernier in 0 position.
	up to memory	± 2 %	}Add 2 % in MIN/MAX mode.
	-Non linearity acc. to IEC 351	3 %	
	additional error	± 15 %	Vernier not in 0 position.
3.3.7	Dynamic range	10 div	
3.3.8	D.c. offset control		Related to BNC input.
	-Range (± 5%)		Input voltage within the limits of 3.3.5.
	Att. @ 5 mV/div ...20 mV/div	± 5 V	}In AUTO OFFSET, the }offset is automatically }controlled such, that }average d.c. level of }signal is presented at }screen centre (± }2 div), provided signal }is within offset range. }Shift is set to zero }(mid) level.
	Att. @ 50 mV/div ...0,2 V/div	± 50 V	
	Att. @ 0,5 V/div ...5 V/div	± 300 V	
	-Resolution (± 5%)		
	Att. @ 5 mV/div ...20 mV/div	5 mV	
	Att. @ 50 mV/div ...0,2 V/div	50 mV	
	Att. @ 0,5 V/div ...5 V/div	0,5 V	
3.3.9	Shift range	± 5 div	From screen centre.

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.3.10	Frequency response (in 50 ohm position)		Z source: 50 Ohm
	-Lower transition point of BW		
	Input coupling in DC position	d.c.	
	Input coupling in AC position	$\leq$ 10 Hz	
	-Upper transition point of BW (Ambient: 15..35°C)	$\geq$ 300 MHz (-3 dB)	Deviation max. 30 MHz for ambient: 0...50°C.
3.3.11	Freq. resp. (In hi.Z pos. through probe)		Z source = 25 Ohm. Probe according to 3.19.
	-Lower transition point of BW		
	Input coupling in DC position	d.c.	
	Input coupling in AC position	$\leq$ 1 Hz	
	-Upper transition point of BW (Ambient: 15..35°C)	$\geq$ 300 MHz (-3 dB)	Deviation max. 30 MHz for ambient: 0...50°C.
3.3.12	Bandwidth limiter		
	-Starting point of HF rejection	20 MHz (-3 dB)	
	-Slope	6 dB/octave	
3.3.13	Pulse response (in 50 Ohm position) (exclusive first mm after transient)		Z source = 50 Ohm; measured over central 6 div.
	-Rise time (Ambient: 15..35°C)	$\leq$ 1,1 ns	(Calculated from bandwidth x Rise time = 0,35). Add max. 0,25 ns for ambient: 0...50°C.

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.3.14	Pulse resp. (in hi.Z pos. through probe) (exclusive first mm after transient)		Z source: = 50 Ohm; measured over central 6 div. Probe according to 3.19.
	-Rise time (Ambient: 15..35°C)	$\leq$ 1,1 ns	(Calculated from bandwidth x Rise Time = 0,35). Add max. 0,25 ns for ambient: 0...50°C.
3.3.15	Max. base line instability		
	-Jump (Ambient 15..35°C):		Add 25 % for ambient: 0...50°C.
	when switching to added mode	0,3 div	
	when switching to MIN / MAX mode	0,5 div	
	between any V/div positions	0,15 div	
	when actuating inverter switch	0,3 div	
	between AC, 0 and DC position	0,1 div	
	when rotating vernier	0,6 div	Input externally grounded.
	between any time/div positions	0,6 div	
	when switching to magn. x5	0,5 div	
	-Drift	0,1 div/h	}
	-Temperature coefficient	$\pm$ 0,05 div/K	}Measured in 20 mV/div }position. }

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.3.16	Common mode rejection ratio		Both channels @ same attenuator setting; vernier for V/div setting adjusted for optimal CMMR at 10 kHz measured with max. 8 div input signal on each channel, (± 4 div around zero).
	-@ 1 MHz	100:1	
	-@ 50 MHz	20:1	
3.3.17	MIN / MAX function		Time base setting 5 us/div ... 360 s/div. Average switched off.
	-Accuracy > 50 %	@ pulse > 3 ns	
	-Reset time	20 ns	
3.3.18	Average		Average formula after the first front change (MIN / MAX switched off).
	Constant is max.	64x	$So(n)=So(n-1)+\frac{Sn-So(n-1)}{C}$
		32 x or off	In ROLL mode.
3.3.19	Cross talk (according to IEC 351)	<-30 dB @ 100 MHz <-50 dB @ 2 MHz	

3

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.4	TIME BASE		
3.4.1	Modes	Recurrent Single shot Single scan Multiple shot Multiple scan Roll Save/Stop on difference	 Up to 4 shots. Up to 4 scans. Can be stopped manually or by trigger.
3.4.2	Time coefficients		
	-In recurrent	5 ns/div...5 s/div	
	-In single scan and multiple scan	5 ns/div...50 ns/div	
	-In single shot and multiple shot	100 ns/div...5 s/div	
	-In roll mode	50 ms/div...360 s/div	
	-With EXT CLOCK	Depending on clock frequency	Input via EXT CLOCK, every clock pulse a sample is taken, so for single channel 4k samples are stored and for dual channel 2 times 2k samples.
	-Error limit (Ambient 15..35 ^{o}C)		
	In equivalent time mode	$\pm$ 4 %	
	In real time mode	$\pm$ 1 %	Add 0,5 % for ambient: 0...50^{o}C.
	Up to memory	$\pm$ 0,01 %	
3.5	TRIGGER		
3.5.1	Sources		
	-Signal trigger	Channel A Channel B EXT LINE	
	-Events	EXT	Serves as delay to signal trigger.
3.5.2	Input connectors	BNC	

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.5.3	Input impedance of EXT trigger inputs		
	-R parallel	1 M Ohm ± 1 %	In DC position of input coupling.
	-C parallel	14 pF	
	-Max. input capacitance difference	1,5 pF	Difference between channel A, channel B and EXT trigger input.
3.5.4	Coupling		
	-Signal trigger	d.c. a.c. LF rejected HF rejected Auto level TVF	According to CCIR.
	-Clock & events trigger level	TTL ECL Through variable level	Adjustable via menu "trigger coupling" - events.
3.5.5	Max. input voltage (d.c. + a.c. peak)		Instrument should be properly earthed through the protective-earth conductor of the power cord.
	-Clock trigger	300 V	
3.5.6	Signal trigger sensitivity (Ambient 15..35°C)		Add 10 % for ambient: 0...50°C.
	-Channel A or B		
	@ 300 MHz	≤ 4 div	
	@ 200 MHz	≤ 1,5 div	
	@ 30 MHz	≤ 0,5 div	
	-EXT		
	@ 300 MHz	≤ 300 mV	
	@ 200 MHz	≤ 0,1 V	
	@ 30 MHz	≤ 0,05 V	
	-EXT/10		
	@ 300 MHz	≤ 3 V	
	@ 200 MHz	≤ 1 V	
	@ 20 MHz	≤ 1 V	

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.5.7	Slope selection	Positive going Negative going Dual slope	Level adjustable; not effective in random sampling and TVF.
3.5.8	Signal level control range		
	-Channel A or B	± 8 div	} }When not in AUTO position
	-EXT	± 0,8 V	}of trigger mode. }
	-EXT/10	± 8 V	}
	-DUAL	± 5 div	}
	-Any source	Related to peak value	}In AUTO position of trig- }ger mode.
3.5.9	Frequency response		Trigger BW not affected by bandwidth limiter.
	-Lower transition point of BW		Ch. A and Ch. B coupling cascaded with trig. coupl.
	Trigger coupling in DC position	d.c.	
	Trigger coupling in AC position	10 Hz (- 3dB)	
	Trigger coupling in LF reject pos.	50 kHz (- 3 dB)	
	-Higher transition point of BW	see also 3.5.6.	
	Trigger coupling in HF reject pos.	50 kHz (-3 dB)	
3.5.10	Trigger delay		
	-Range	-10...9999 div	}can also be indicated in }time.
	@ 5 ns/div ... 100 ns/div	-10...500 div	} }
	-Number of events	1...9999	
	Max. frequency	5 MHz	
	-Accuracy	± 1 %	
	@ 5 ns/div ... 100 ns/div	± 3 % ± 5 ns	

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.6	MEMORY		
3.6.1	Memory size		
	-Registers	4	Registers #0, #1, #2, #3
	-Register depth	4096 words	
	-Wordlength	10 bits	
3.6.2	Functions	Clear	Register #0 is cleared, incl. pre-trigger memory and blanked if DOTS is selected.
		Save	Contents of register #0 is saved in selected register (#1, #2 or #3).
		Write	Acquired signal is written into register #0.
		Lock	Memory system is locked, including register #0.

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.7	DISPLAY		
3.7.1	Sources	Register #0 Register #1 Register #2 Register #3	} }In any combination. } }
3.7.2	Display expansion		
	-Horizontal		
	Steps:	1x...64x	In Y versus t mode.
		1x...8x	In A versus B mode.
	Vernier ratio	1:2	Continuously variable between steps. Recalculated value is displayed with an accuracy of ± 5 %.
	-Vertical		
	Steps:	0.2x, 1x and 5x	Both in Y versus t and A versus B modes.
3.7.3	Display manipulations	Smooth	Reduces noise by adding a filter in the display section, that is only effective at time base 500 us/div ... 360 s/div.
		Dot join	Linearly interpolated between measured dots.
		Invert	Alle registers can be inverted.
3.7.4	Position range		All channels can be positioned independently.
	-Horizontal	± 5 div	From screen centre.
	-Vertical	± 5 div	From screen centre.

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.8	SETTING MEMORY		
3.8.1	Memory size	Max. 251 front settings	
3.8.2	Functions		
		Save	Actual settings are stored in memory, replacing contents of memory cell indicated on CRT.
		Insert	Actual settings are stored in memory; insertion is after memory cell indicated on CRT.
		Delete	Contents of memory cell indicated on CRT is deleted.
		Recall	Actual settings are replaced by contents of memory cell indicated on CRT. Actual settings are saved in "back-up" memory (= mem. cell #0).
		(Recall) Next	Actual settings are replaced by contents of memory cell indicated on CRT increased by 1. Actual settings are saved in "back-up" memory (= memory cell #0).
		(Recall) Previous	Actual settings are replaced by contents of memory cell indicated on CRT decreased by 1. Actual settings are saved in "back-up" memory (= memory cell #0).

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.9	ANALYZE FACILITIES		
3.9.1	Measure		
	-Amplitude	RMS value Mean value Peak to peak voltage Peak to zero voltage Overshoot Preshoot	} }Including or excluding } }offset voltage }Result calculated from }part between cursors or }markers. }
	-Time	Risetime Pulse width Duty cycle Frequency Phase	
3.9.2	Mathematics		
		Add Subtract Multiply Divide Differentiate Integrate Delay channel	} }Results of calculation }displayed in selected }register and scalable }for optimum display } }
		Histogram	Amplitude density vs. absolute amplitude of an input signal
		Filter	Digital filter of order 3,5,9,17,33,65,129.
3.10	AUTO SETTING		
3.10.1	Settling time	Typical 3 s	During plot, AUTO SET is not possible.
3.10.2	CRT functions		
	-Focus	Not influenced	
	-Trace intens	Not influenced	
	-Text intens	Not influenced	
3.10.3	Display functions		
	-Select	To register #0	
	-X-position	Zero	
	-Y-position	Zero	
	-Invert	Off	Only for register #0.
	-X-expand	*1	Vernier calibrated.
	-Y-expand	*1

	Passive 50 Ohm attenuator	}	
	Passive 75 Ohm in 50 Ohm out attenuator	}Fixed @ 50 Ohm	
	Active current probe	}	
	Active isolation probe	}	
	-Vertical sensitivity setting		
	Passive probe	Not affected	
	Passive attenuator	Not affected	
	Active current probe	20 mV/div	Can be manually changed.
	Active isolation probe	20 mV/div	Can be manually changed.
	-V/div and voltage cursor read out		
	Passive 10:1 probe	10 x higher	}
	Passive 10 x attenuator	10 x higher	}
	Passive 100:1 probe	100 x higher	}Offset read out is changed accordingly.
	Passive 100 x attenuator	100 x higher	}
	Active current probe	In divisions	}
	Active isolation probe	In divisions	}

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.15.3	Analog plot output		
	-Connector	DIN 5 pole 45°	
	-Functions	Screen dump	Included channel identifier.
		Memory dump	Register selectable.
	-Sensitivity	1 V/Full screen ± 3 % 1 V/Full memory ± 3 %	} }Horizontal and vertical. } }
	-Pen lift	TTL compatible	Pen-up is selectable (0 or 1). Open collector output; max. 12 V.
	-Plot time per dot	20 ms .. 2 s	Software selectable. Signal dependent.
	-Plot sequence	Channel A first	In dual channel operation; with more registers starting with the lowest number.
3.16	MECHANICS		
3.16.1	Height		Fits 5E in 19 inch rack.
	-Without feet and accessory pouch	176 mm (6,9 in.)	Add 15. mm (0,6 in.) for feet.
	-Feet and accessory pouch included	250 mm (9,8 in.)	
3.16.2	Width	419 mm (16,5 in.)	Add 46 mm (1,8 in.) for handle.
3.16.3	Depth		
	-Handle excluded	570 mm (22,5 in.)	Add 35 mm (1,4 in.) for protective front cover.
	-With extended handle	670 mm (26,4 in.)	
3.16.4	Mass	18 kg	
3.16.5	Finish	Epoxy powder coated	
3.16.6	Printed circuit boards	Glass laminate epoxy	
3.16.7	Cooling	Fan aided convection	Maintenance free. To allow air convection, at least 1,5 cm free space is required below the oscilloscope.

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.17	ENVIRONMENTAL		
3.17.1	General		
	The characteristics are valid only if instrument is checked inaccordance with the official checking procedures. Details on these procedures and failure criteria are supplied on request.		
3.17.2	Meets environmental requirements of	MIL-T-28800C Type III Class 5, Style D	
3.17.3	Temperature		Memory back-up batteries removed from instrument, unless batteries meet temperature specifications (see also 3.15.1).
	-Operating		
	Min. low temperature	0°C	Cf. MIL-T-28800D par. 3.9.2.3 tested cf. par. 4.5.5.1.1.
	Max. high temperature	+ 50°C	Cf. MIL-T-28800D par. 3.9.2.4 tested cf. par. 4.5.5.1.1.
	-Non operating (Storage)		
	Min. low temperature	-40°C	Cf. MIL-T-28800D par. 3.9.2.3 tested cf. par. 4.5.5.1.1.
	Max. high temperature	+ 75°C	Cf. MIL-T-28800D par. 3.9.2.4 tested cf. par. 4.5.5.1.1.
3.17.4	Maximum humidity		Cf. MIL-T-28800D par. 3.9.2.2 tested cf. par. 4.5.5.1.1.
	-Operating and non-operating (Storage)	95% Relative humidity	

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.17.5	Maximum altitude		Cf. MIL-T-28800D par. 3.9.3 tested cf. par. 4.5.5.2. Memory Back-up batteries removed from instrument, unless batteries meet maximum altitude specs.
	-Operating	4,5 km (15000 feet)	Maximum operating temperature derated 3 °C for each km (for each 3000 feet) above sea level.
	-Non-operating (storage)	12 km (40000 feet)	
3.17.6	Vibration (Operating)		Cf. MIL-T-28800D par. 3.9.4.1 tested cf. par. 4.5.5.3.1.
	-Freq. 5...15 Hz		
	Sweep time	7 min	
	Excursion (pk to pk)	1,5 mm	
	Max acceleration	7 m/s^2 (0,7 x g)	@ 15 Hz.
	-Freq. 5...25 Hz		
	Sweep time	3 min	
	Excursion (pk to pk)	1,0 mm	
	Max acceleration	13 m/s^2 (1,3 x g)	@ 25 Hz.
	-Freq. 25...55 Hz		
	Sweep time	5 min	
	Excursion (pk to pk)	0,5 mm	
	Max acceleration	30 m/s^2 (3,0 x g)	@ 55 Hz.
	-Resonance dwell	10 min	@ each resonance freq. (or @ 33 Hz if no resonance was found). Excursion cf. 3.17.6.
3.17.7	Shock (Operating)		Cf. MIL-T-28800D par. 3.9.5.1 tested cf. par. 4.5.5.4.1.
	-Amount of shocks		
	total	18	
	each axis	6	(3 in each direction).
	-Shock wave form	half sine wave	
	-Duration	11 ms	
	-Peak acceleration	300 m/s^2 (30 x g)	

	CHARACTERISTIC	SPECIFICATION	ADDITIONAL INFORMATION
3.17.8	Bench handling		Cf. MIL-T-28800D par. 3.9.5.3 tested cf. par. 4.5.5.4.3.
	-Meets requirements of:	MIL-STD-810 methode 516, proced. V	
3.17.9	Salt atmosphere		Cf. MIL-T-28800D par. 3.9.8.1 tested cf. par. 4.5.6.2.1.
	-Structural parts meet requirements of:	MIL-STD-810 methode 509, proced. I salt solution 20%	
3.17.10	EMI (Electro magnetic interference) meets requirements of:	MIL-STD-461	Applicable requirements of Part 7: CE03, CE07, CS01, CS02, CS06, RE02, RS02, RS03.
3.17.11	Magnetic radiated susceptibility		Tested conforming IEC 351-1 par. 5.1.3.1.
	-Maximum deflection factor	7 mm/mT (0,7 mm/gauss)	Measured with instrument in a homogeneous magnetic field (in any direction with respect to instrument) with a flux intensity (peak to peak value) of 1,42 mT (14,2 gauss) and of symmetrical sine wave form with a frequency of 45...66 Hz.
3.17.12	Packing		
	Meets requirements of:	NLN-L88	
3.17.13	Transportation		
	Meets requirements of:	AN-D628	
	-Packaged transportation drop		
	meets requirements of:	Nat. safe transp. ass. procedure 1A-B-2	
	-Packed transportation vibration		
	meets requirements of:	Nat. safe transp. ass. procedure 1A-B-1

PERFORMANCE CHECK

PERFORMANCE CHECK

CONTENTS

4.0 Performance check..... 4-1
4.1 General information..... 4-1
4.2 Recommended test and calibration equipment..... 4-2
4.3 Preliminary settings..... 4-2
4.4 Checking procedure..... 4-3

4.0 PERFORMANCE CHECK

4.1 GENERAL INFORMATION

WARNING: Before switching on, ensure that the instrument has been installed in accordance with the Installation Instructions outlined in chapter 3.0 of the Operating Manual.

This procedure is intended to:

- check the instruments´specification.
- be used for incoming inspection to determine the acceptability of newly purchased instruments and/or recently recalibrated instruments.
- check the necessity of recalibration after the specified recalibration intervals.

NOTE: The procedure does not check every facet of the instrument´s calibration; rather, it is concerned primarily with those parts of the instrument which are essential to measurement accuracy and correct operation. Removing the instrument covers is not necessary to perform this procedure. All checks are made from the outside of the instrument.

If the test is started within a short period after switching on, bear in mind that steps may be out of specification, due to insufficient warming-up time.

Warming-up time under average conditions is 30 minutes.

The performance checks are made with a stable, well-focussed, low-intensity display. Unless otherwise noted, adjust the intensity and level controls as needed.

NOTES :

* At the start of every check, the controls always occupy the preliminary settings AUTO SET position, unless otherwise stated.

* The input voltage has to be supplied to the channel A input; unless otherwise stated.
Unless otherwise stated, the switches TIME/DIV, SHIFT A and B, X-POSITION, TRACE INTENS and TEXT INTENS must be put in such a position that a good read-out of the phenomena of interest is obtained.

* Tolerances given are for the instrument under test and do not include test equipment error.

* The given input impedance of the oscilloscope under test (being 50 ohm or 1 megaohm) are valid if the generator types are used that are given in chapter 13.1 "Recommended test and calibration equipment". If you use other types, the input impedances may be different.

* For some checks, we make use of service routines. If you want additional information concerning these service routines refer to chapter 11 "Trouble shooting".

* In some checks in this chapter channel B is mentioned between brackets behind channel A. It is advised to perform the channel A checks first. After that the checks for channel B can be done.

4.2 RECOMMENDED TEST AND CALIBRATION EQUIPMENT

A complete list of all material necessary for both this performance check and also the adjusting procedure is given in chapter 13.1 in this manual.

4.3 PRELIMINARY SETTINGS

- Switch the oscilloscope on.
- Check that all the LEDs in the front panel are on for 1 sec. during the power up routine of the instrument´s microprocessor.
- Press AUTO SET.
- Check that after adjustment of TEXT INTENS and TRACE INTENS the read-out information and a horizontal line become visible at the CRT-screen.

A.	POWER SUPPLY	
	IMPORTANT	The measurements of the power supply must be done with life voltages. Therefore it is strongly advised to use a variable mains transformer with isolated primary and secondary windings. Nevertheless, these tests must only be done by a qualified technician who is aware of the danger involved.
A.1	SUBJECT	Mains voltage range.
	TEST EQUIPMENT	Variable mains voltage transformer (and digital multimeter).
	SETTINGS	- Connect the oscilloscope (switched off) to the output of the variable mains voltage transformer. If the transformer has no output voltage read-out, you must connect the digital multimeter (a.c. voltage range) to the outputs of the transformer. - Connect the variable mains transformer to the mains and adjust the output voltage.
	REQUIREMENTS	- Check that the oscilloscope starts up normally when switched on at any voltage in the range 90...264 V (a.c). Preferred check points are 110, 220 and 240 V (a.c.).
	MEASURING RESULTS	.....
	SETTINGS	- Switch the oscilloscope on at a mains voltage between 90...264 V (a.c.). - Connect the input of Ch. A with the CAL voltage. - Press AUTO SET. - Adjust AMPL/DIV of Ch. A, TIME/DIV and other controls to a nice display of the CAL output voltage.
	REQUIREMENTS	- Check that the display stays stable over the mains voltage range 90...264 V (a.c.).
	MEASURING RESULTS	.....
		- Switch the oscilloscope off and disconnect the variable transformer from the mains.

A.2 SUBJECT

Mains voltage current.

TEST EQUIPMENT

Variable mains voltage transformer and digital multimeter.

SETTINGS

- Connect the oscilloscope to the variable mains transformer. In one of the mains conductors of the oscilloscope the digital multimeter (a.c. current range) must be present.
- Connect the transformer to the mains and switch the oscilloscope on. Graticule illumination must be on.

REQUIREMENTS

- Measure the current drain of the oscilloscope according to the table below (rms value). This current depends on the applied mains voltage and from the fact if the IEEE option is installed or not. The current with installed option is mentioned between brackets.

Mains voltage:	Current:
110 V (a.c.)	1,2 A (1,4 A)
220 V (a.c.)	0,55 A (0,65 A)
240 V (a.c.)	0,5 A (0,6 A)

MEASURING RESULTS .....

Disconnect the variable mains transformer from the mains and connect the oscilloscope directly to the mains voltage.

B.	C.R.T. DISPLAY SECTION	
B.1	SUBJECT	Trace distortion.
	TEST EQUIPMENT	LF sine wave generator.
	SETTINGS	- Press AUTO SET. - Select input coupling GROUND. - Shift the Ch. A trace in the vertical mid of the screen.
	REQUIREMENTS	- Check that the Ch. A trace is exactly in parallel with the horizontal graticule lines. - If not correct this with the screwdriver control TRACE ROT. - Shift the Ch. A trace upwards and downwards and check if the deviation from the straight line does not exceed 0,1 div measured outside the central 8x10 div.
	MEASURING RESULTS	.....
	SETTINGS	- Press AUTO SET. - Apply a 2 kHz/1,6 V (pp) sine wave voltage to the Ch. A input socket. - Adjust the generator´s output voltage to 8 div vertical deflection. - Select vertical display of Ch. A and B. - Shift the Ch. A and Ch. B display in the vertical mid of the screen. - Select in the DISPLAY section A versus B display and switch register Ø on.
	REQUIREMENTS	- Check that a vertical line of 8 div is displayed. - Shift this line to the left and the right by means of X-POSITION and check if the deviation from the straight line does not exceed 0,1 div outside the central 8x10 div.
	MEASURING RESULTS	.....

	SETTINGS	- Shift the vertical line in the horizontal mid of the screen.
	REQUIREMENTS	- Check that the angle between the vertical graticule lines and the displayed line does not exceed 0,5 degree.
	MEASURING RESULTS	.....

C.	VERTICAL DEFLECTION	
C.1	SUBJECT	Input coupling Ch. A (B).
	TEST EQUIPMENT	LF sine wave generator.
	SETTINGS	- Apply a 1 kHz/120 mV (pp) to input socket A (B). - Press AUTO SET. - Select 50 ohm and DC input coupling. - Adjust AMPL/DIV to 20 mV/div for Ch. A (B) and the generator to an output voltage of 6 div. - Lower the generator frequency to 10 Hz. Vertical display must stay 6 div. - Select DC trigger coupling and adjust the LEVEL control for a triggered display. - Select 20 ms/div with the TIME/DIV control. - Select AC input coupling for Ch. A (B).
	REQUIREMENTS	- Check that the amplitude of the displayed signal is 4,3 div or higher.
	MEASURING RESULTS	.....
	SETTINGS	- Select GROUND input coupling for Ch. A (B).
	REQUIREMENTS	- Check that only a straight line is displayed.
	MEASURING RESULTS	.....

C.2 SUBJECT — Vertical deflection coefficients Ch. A (B).

TEST EQUIPMENT — Square wave calibration generator.

SETTINGS
- Apply a calibrated square wave signal of 1 kHz/20 mV (pp) to input Ch. A (B).
- Press AUTO SET.
- Select DC input coupling and 1 megaohm input impedance.
- Select 5 mV/div with the Ch. A (B) AMPL/DIV control.

REQUIREMENTS
- Check if the amplitude of the signal is 4 div (+or- 2%).

MEASURING RESULTS .....

4

SETTINGS AND REQUIREMENTS
- Increase the Ch. A (B) input signal according to the following table and check the accuracy of the displayed signal.

Input voltage (pp)	Y AMPL setting	Requirements	Measuring results
50 mV	10 mV	5 div.(+or- 2%)	.....
0,1 V	20 mV	5 div.(+or- 2%)	.....
0,2 V	50 mV	4 div.(+or- 2%)	.....
0,5 V	100 mV	5 div.(+or- 2%)	.....
1 V	200 mV	5 div.(+or- 2%)	.....
2 V	500 mV	4 div.(+or- 2%)	.....
5 V	1 V	5 div.(+or- 2%)	.....
10 V	2 V	5 div.(+or- 2%)	.....
20 V	5 V	4 div.(+or- 2%)	.....

SETTINGS
- Select 5 V/div input sensitivity for Ch. A (B).
- Turn the VARIABLE gain of Ch. A (B) into the UNCAL position towards an input sensitivity of 10 V/div.

REQUIREMENTS — Check that the accuracy of the vertical deflection is within +or- 15%.

MEASURING RESULTS .....

Put the VARIABLE gain back in the calibrated position.

C.3 SUBJECT — Input impedance and capacitance Ch. A (B).

TEST EQUIPMENT — Square wave calibration generator and 1 megaohm/14 pF dummy probe 2:1.

SETTINGS
- Apply a calibrated square wave signal of 1 kHz/50 mV (pp) to input Ch. A (B) via the dummy probe.
- Press AUTO SET.
- Select 5 mV/div with the Ch. A (B) AMPL/DIV control.
- Select DC input coupling and 1 megaohm input impedance.

REQUIREMENTS
- Check if the amplitude of the signal is 4 div (+or- 2%) and that it is free from overshoot or undershoot.

MEASURING RESULTS .....

SETTINGS AND REQUIREMENTS
- Increase the Ch. A (B) input signal according to the following table and check the signal accuracy and pulse response.

Input voltage(pp) via dummy probe	Y AMPL setting	Requirements	Measuring results
0,1 V	10 mV	5 div.(+or- 2%)	.....
0,2 V	20 mV	5 div.(+or- 2%)	.....
0,5 V	50 mV	5 div.(+or- 2%)	.....
1 V	100 mV	5 div.(+or- 2%)	.....
2 V	200 mV	5 div.(+or- 2%)	.....
5 V	500 V	5 div.(+or- 2%)	.....
10 V	1 V	5 div.(+or- 2%)	.....
20 V	2 V	5 div.(+or- 2%)	.....
50 V	5 V	5 div.(+or- 2%)	.....

C.4

SUBJECT	Protection of 50 ohm input impedance Ch. A(B).
TEST EQUIPMENT	LF square wave generator (source impedance 50 ohm).
SETTINGS	- Select 1 megaohm input impedance. - Apply a square wave signal of 1 kHz/6 V (pp) to the Ch. A (B) input. - Press AUTO SET. - Select 2 V/div with the Ch. A (B) AMPL/DIV control.
REQUIREMENTS	- Check if it is possible to switch Ch. A (B) from 1 megaohm to 50 ohm input impedance. This can be observed on the CRT because the signal amplitude halves and the softkey text "50ohm" becomes intensified.
MEASURING RESULTS	.....
SETTINGS	- Keep the instrument in 50 ohm position. - Increase the output signal from the generator to 15 V (pp) (into 50 ohm). - Check if the instrument switches automatically back to 1 megaohm input impedance. The softkey text "1Mohm" becomes intensified now and the displayed signal amplitude doubles.
MEASURING RESULTS	.....
SETTINGS	- Keep the instrument in 1 megaohm position. - Adjust the generator output voltage to 15 V (pp) (into 1 megaohm).
REQUIREMENTS	- Check that the Ch. A (B) input impedance cannot be switched to 50 ohm.
MEASURING RESULTS	.....

C.5	SUBJECT	Vertical dynamic range Ch. A (B).
	TEST EQUIPMENT	Constant amplitude sine wave generator.
	SETTINGS	- Apply a sine wave of 300 MHz/2 V (pp) to the Ch. A (B) input. Select 50 ohm input impedance for Ch. A (B). - Press AUTO SET. - Select 500 mV/div with the Ch. A (B) AMPL/DIV control. - Re-adjust the output signal of the generator so that 4 div are displayed. - Select 200 mV/div with the Ch. A (B) AMPL/DIV control.
	REQUIREMENTS	- Shift the displayed sine wave upwards and downwards and check that it is free from distortion.
	MEASURING RESULTS	.....

C.6	SUBJECT	Vertical bandwidth Ch. A (B) in 50 ohm and 1 megaohm positions.
	TEST EQUIPMENT	Constant amplitude sine wave generator.
	SETTINGS	- Apply a sine wave of 50 kHz/120 mV (pp) to the Ch. A (B) input. - Press AUTO SET. - Select 50 ohm input impedance (external termination resistor not necessary). - Select 20 mV/div with the Ch. A (B) AMPL/DIV control. - Re-adjust the output signal of the generator so that exactly 6 div are displayed.
	REQUIREMENTS	- Check that the displayed amplitude via Ch. A (B) is always 4,3 div or higher over the complete bandwidth range until 300 MHz. - Adjust -if necessary- the TIME/DIV knob for a well-defined sine wave.
	MEASURING RESULTS	.....

	TEST EQUIPMENT	Constant amplitude sine wave generator, 50 ohm termination resistor and adapter BNC/probe tip.
	SETTINGS	- Connect the termination resistor directly to the output socket of the sine wave generator. - Connect the 10:1 attenuator probe PM8929/09 to input A (B) of the oscilloscope. This probe must be correctly compensated according to the procedure given in chapter 8.1.1.4 in the operating manual. - Put the probe tip via the BNC/probe tip adapter in the 50 ohm termination at the generator. - Re-adjust the generator so that exactly 6 div are displayed at a frequency of 50 kHz.
	REQUIREMENTS	- Check that the displayed amplitude via Ch. A (B) is always 4,3 div or higher over the complete bandwidth range until 300 MHz. - Adjust -if necessary- the TIME/DIV knob for a well-defined sine wave.
	MEASURING RESULTS	.....
C.7	SUBJECT	Bandwidth limiter Ch. A (B).
	TEST EQUIPMENT	Constant amplitude sine wave generator.
	SETTINGS	- Apply a sine wave of 20 MHz/120 mV (pp) to the Ch. A (B) input. - Press AUTO SET. - Select 50 ohm input impedance. - Select 20 mV/div with the Ch. A (B) AMPL/DIV control. - Re-adjust the output signal of the generator so that exactly 6 div are displayed.
	REQUIREMENTS	- Switch the instrument´s bandwidth limiter on (via vertical MODE and softkey PROCESSING). - Check that the amplitude of the displayed signal is 4,3 div.
	MEASURING RESULTS	.....

C.8 SUBJECT

Pulse response Ch. A (B) in 50 ohm and 1 megaohm positions.

TEST EQUIPMENT

Square wave calibration generator.

SETTINGS

- Apply the fast-rise output of the generator to the Ch. A (B) input. Maximum output voltage must be selected and a frequency of 1 MHz.
- Press AUTO SET.
- Select 50 ohm and DC coupled input
- Select 200 mV/div with the Ch. A (B) AMPL/DIV control. Adjust the generator output voltage to a deflection of exactly 6 or 5 div.
- Put the signal exactly in the vertical mid of the screen.
- Select 5 ns/div with the TIME/DIV control.

REQUIREMENTS

- Check the pulse response during first 10 ns: the pulse abberations must not exceed +or- 6%. This means abberations of +or- 0,3 div (0,35 div) at an pulse amplitude of 5 div (6 div).
- For an accurate measurement it is necessary that the rise-time of the generator signal is 1 ns. Eventual pulse distortion from the generator must also be taken into account.

MEASURING RESULTS .....

TEST EQUIPMENT

Square wave calibration generator, 50 ohm termination resistor and adapter BNC/probe tip.

SETTINGS

- Connect the termination resistor directly to the fast-rise output of the generator.
- Connect the 10:1 attenuator probe PM8929/09 to input A (B) of the oscilloscope. This probe must be correctly compensated according to the procedure given in chapter 8.1.1.4 in the operating manual.
- Put the probe tip via the BNC/probe tip adapter in the 50 ohm termination at the generator.
- Select 200 mV/div with the Ch. A (B) AMPL/DIV control. Adjust the generator output voltage to a deflection of 6 or 5 div.
- Put the signal exactly in the vertical mid of the screen.
- Re-adjust the generator so that 5 or 6 div are displayed on the screen.

	REQUIREMENTS	Check the pulse response during the first 10 ns: the pulse abberations must not exceed +or- 6%. Other conditions identical to the check with 50 ohm input impedance.
	MEASURING RESULTS	.....

C.9	SUBJECT	Base line instability.
	TEST EQUIPMENT	BNC/banana adaptor PM9051 with interconnected outlets
	SETTINGS	- Press AUTO SET without input signals. - Select Ch. A and B for vertical display. - Position the A and B lines in the vertical mid of the screen. - Select function ADD.
	REQUIREMENTS	- Check that the line that should be in the vertical mid of the screen does not have a displacement of more that 0,3 div.
	MEASURING RESULTS	.....

	SETTINGS	- Select Ch. A and B for vertical display. - Position the Ch. A line 1 div. above the vertical mid of the graticule and the Ch. B line 1 div. under the vertical mid. - Select softkey function PROCESSING. - Switch softkey function MIN MAX repeatedly on and off.
	REQUIREMENTS	- Check that the Ch. A and B lines do not jump more than 0,5 div.
	MEASURING RESULTS	.....

SETTINGS	- Switch function MIN MAX off. - Switch up and down through the complete range of the Ch. A and B AMPL/DIV control. This happens if you keep the knob fixed in one position.
REQUIREMENTS	- Check that the Ch. A and B lines do not jump more than 0,15 div.
MEASURING RESULTS	.....

SETTINGS	- Switch the softkey functions A-INVERT and B-INVERT repeatedly on and off.
REQUIREMENTS	- Check that the Ch. A and B lines do not jump more than 0,3 div.
MEASURING RESULTS	.....

SETTINGS	- Switch the INVERT functions off. - Switch the Ch. A and B input couplings repeatedly between AC, DC and GROUND.
REQUIREMENTS	- Check that the Ch. A and B lines do not jump more than 0,1 div.
MEASURING RESULTS	.....

SETTINGS	- Ground the Ch. A (B) input externally by means of a BNC/banana adapter with interconnected outlets. - Select DC input coupling for Ch. A and B. - Turn the controls VARIABLE gain Ch. A and B repeatedly between their extreme positions.
REQUIREMENTS	- Check that the Ch. A and B line do not move more than 0,6 div.
SETTINGS	- Remove the BNC/banana adaptor. - Put the VARIABLE gain controls in their CAL position. - Shift the Ch. A and B line exactly in the vertical mid of the screen. - Switch the MAGNIFY function repeatedly between Yx1 and Yx5.

	REQUIREMENTS	- Check that the jump of the Ch. A and B line does not exceed 0,5 div.
	MEASURING RESULTS	.....

C.10	SUBJECT	Common mode rejection ratio.
	TEST EQUIPMENT	Constant amplitude sine wave generator, terminator 50 ohm and T-piece.
	SETTINGS	- Apply a 50 kHz sine wave of 1,6 V (pp) to input A and B via equal cables. The generator must be terminated with an external 50 ohm piece. Input impedance of oscilloscope channels is 1 megaohm. - Press AUTO SET. - Select 200 mV/div with the Ch. A and B AMPL/DIV controls. - Position both signals exactly in the vertical mid of the screen. - Select B-INVERT mode and ADD-mode. - Adjust either the VARIABLE gain control of Ch. A or B for minimal amplitude of the displayed signal.
	REQUIREMENTS	- Increase the generator´s frequency to 1 MHz (50 MHz). - Check that the amplitude of the displayed signal does not exceed 0,08 div (0,4 div).
	MEASURING RESULTS	.....

C.11	SUBJECT	Average function.
	TEST EQUIPMENT	Constant amplitude sine wave generator and LF sine wave generator.
	SETTINGS	- Select 50 ohm input impedance for Ch. A and B. - Apply a LF sine wave of 1 kHz/1,2 V (pp) to the Ch. A input. - Press AUTO SET. - Select 200 mV/div for Ch. A. - Select trigger COUPLING modes AC and HF reject. - Apply a HF sine wave of 100 MHz/0,2 V (pp) from the constant amplitude generator to the Ch. B input socket. - Ch. B input sensitivity must be 200 mV/div. - Select ADD mode for vertical display. The display now shows the 1 kHz/6 div sine wave with much noise superimposed.
	REQUIREMENTS	- Select via vertical mode and processing the average mode. Now you can select the AVERAGE value C between 2...64. The higher C is choosen, the cleaner the display becomes: the noise is eliminated. A high C value has the disadvantage that the correction action lasts longer.
	MEASURING RESULTS	.....

D. HORIZONTAL DEFLECTION

D.1	SUBJECT	Deflection coefficients time-base.
	TEST EQUIPMENT	Time marker generator.
	SETTINGS	- Press AUTO SET. - Select DC input coupling and 50 Ohm input impedance for Ch. A. - Select DC trigger coupling. - Apply the output signal of the time marker generator to input Ch. A. - Adjust the LEVEL control for a triggered display.
	REQUIREMENTS	- Check the deflection coefficient error according to the table below.

Time markers(pp) pulse frequency	Time-base setting .../div	Max. coefficient error	Measuring results
5 s	5 s	+or- 1%	.....
2 s	2 s	+or- 1%	.....

5 ns	5 ns	+or- 4%	.....

- Remove the input signal.

D.2 SUBJECT — Time-base line instability.

TEST EQUIPMENT — -

SETTINGS
- Press AUTO SET.
- Position the Ch. A base line in the vertical mid of the screen.
- Switch up and down through the complete range of the TIME/DIV switch. This happens if you keep the knob fixed in one position.

REQUIREMENTS
- Check that the vertical jump of the line does not exceed 0,6 div.

MEASURING RESULTS .....

D.3 SUBJECT — Trigger sensitivity via Ch. A (B).

TEST EQUIPMENT — Constant amplitude sine wave generators.

SETTINGS
- Apply a sine wave of 50 kHz/0,5 V (pp) to the Ch. A (B) input socket. Input impedance 50 ohm.
- Press AUTO SET.
- Increase the signal frequency to 30 MHz.
- Select 20 ns/div for the time-base.
- Decrease the signal amplitude to 0,5 div (pp) displayed on the screen.

REQUIREMENTS
- Check that the signal of 30 MHz/0,5 div (pp) is correctly triggered via Ch. A (B). The pilot lamp NOT TRIG´D must be off.

MEASURING RESULTS .....

SETTINGS
- Increase the signal frequency to 200 MHz.
- Select 5 ns/div for the time-base.
- Increase the signal amplitude to 1 div (pp).

REQUIREMENTS
- Check that the signal of 200 MHz/1 div (pp) is correctly triggered via Ch. A (B). The pilot lamp NOT TRIG´D must be off.

MEASURING RESULTS .....

SETTINGS
- Change the constant amplitude sine wave generator into the type that is able to deliver 300 MHz into Ch. A (B).
- Adjust the amplitude of the generator to 3 div (pp).

REQUIREMENTS
- Check that the signal of 300 MHz/3 div (pp) is correctly triggered via Ch. A (B). The pilot lamp NOT TRIG´D must be off.

MEASURING RESULTS .....

D.4 SUBJECT

Trigger sensitivity via EXT (EXT:10).

TEST EQUIPMENT

Constant sine wave generators, terminator 50 ohm and T-piece.

SETTINGS

- Apply a 50 kHz sine wave of 100 mV (pp) (1 V (pp)) to input Ch. A and EXT TRIG. The generator must be terminated with an external 50 ohm terminator. From this terminator, the signal is supplied to EXT TRIG and Ch. A via a T-piece and two equal coaxial cables.
- Select 1 megaohm input impedance for Ch. A.
- Press AUTO SET.
- Select 20 mV/div (200 mV/div) for Ch. A.
- Trigger the time-base on SOURCE EXT (EXT:10).
- Increase the signal frequency to 30 MHz.
- Select 20 ns/div for the time-base.
- Decrease the signal amplitude to 50 mV (pp) (500 mV (pp)). This can be monitored via Ch. A.

REQUIREMENTS

Check that the signal of 30 MHz/50 mV (pp) (500 mV (pp)) is correctly triggered via EXT (EXT:10).
The pilot lamp NOT TRIG´D must be off.

MEASURING RESULTS

.....

SETTINGS

- Increase the signal frequency to 200 MHz.
- Select 5 ns/div for the time-base.
- Increase the signal amplitude to 100 mV (pp) (1 V (pp)).

REQUIREMENTS

- Check that the signal of 200 MHz/100 mV (pp) (1 V (pp)) is correctly triggered via EXT (EXT:10).
  The pilot lamp NOT TRIG´D must be off.

MEASURING RESULTS

.....

	SETTINGS	- Change the constant amplitude sine wave generator into the type that is able to deliver a signal of 300 MHz/300 mV (pp) (3 V (pp)) into the EXT TRIG input. - Terminate the generator´s output signal with an external termination piece and apply it to the EXT TRIG input. - Adjust the generator´s output signal ot exactly 300 mV (pp) (3 V (pp)). - Select EXT (EXT:10) as a trigger source.
	REQUIREMENTS	- Check that the sine wave of 300 MHz/300 mV (pp) (3 V (pp)) triggers the time-base correctly. The pilot lamp NOT TRIG´D must be off then.
	MEASURING RESULTS	.....
D.5	SUBJECT	Level control range Ch. A (B).
	TEST EQUIPMENT	LF sine wave generator.
	SETTINGS	- Apply a sine wave of 50 kHz/1,6 V (pp) to Ch. A (B). - Select 50 ohm input impedance for Ch. A (B). - Press AUTO SET. - Select 200 mV/div with the Ch. A and B AMPL/DIV controls. - Adjust the generator output voltage to a vertical display of 8 div. - Select AC trigger coupling. - Select 100 mV/div with the Ch. A and B AMPL/DIV controls.
	REQUIREMENTS	- Shift the via Ch. A (B) displayed sine wave upwards and downwards and check that the range of the LEVEL control lies at least between top and bottom of the sine wave.
	MEASURING RESULTS	.....

D.6

SUBJECT	Level control range via EXT (EXT:10).
TEST EQUIPMENT	LF sine wave generator, terminator 50 ohm and T-piece.
SETTINGS	- Apply a 50 kHz sine wave of 1,6 V (pp) (16 V (pp)) to input Ch. A and EXT TRIG. The generator must be terminated with an external 50 ohm terminator. From this terminator the signal is supplied to EXT TRIG and Ch. A via a T-piece and two equal coaxial cables. - Select 1 megaohm input impedance for Ch. A. - Press AUTO SET. - Select 200 mV/div (2 V/div) for Ch. A. - Trigger the time-base on EXT (EXT:10). - Select AC trigger coupling. - Adjust the generator for a vertical display via Ch. A of exactly 8 div.
REQUIREMENTS	- Check that the range of the LEVEL control is at least between the top and bottom of the displayed sine wave.
MEASURING RESULTS	.....

D.7 SUBJECT — Bandwidth of trigger filters.

TEST EQUIPMENT — LF sine wave generator, terminator 50 ohm and T-piece.

SETTINGS
- Apply a 1 kHz sine wave of 50 mV (pp) to input Ch. A and EXT TRIG. The generator must be terminated with an external 50 ohm terminator. From this terminator the signal is supplied to EXT TRIG and Ch. A via a T-piece and two equal coaxial cables.
- Select 1 megaohm input impedance for Ch. A.
- Press AUTO SET.
- Select 20 mV/div and DC input coupling for Ch. A and check that 2,5 div signal are displayed. If necessary the generator output voltage must be re-adjusted.
- Select EXT as trigger source.
- Select AC and HF REJECT trigger coupling and adjust the LEVEL control for a well-triggered display.
- NOT TRIG´D lamp must be off.
- Increase the generator´s frequency to 100 kHz. Time-base in position 5 us/div.

REQUIREMENTS
- Check that there is no position of the LEVEL control that gives a triggered display.
- Increase the generator´s output voltage to 100 mV (+6 dB). This results in 5 div signal amplitude on the screen.
- Check that the LEVEL can be adjusted to a triggered display.

MEASURING RESULTS .....

SETTINGS
- Decrease the generators frequency to 5 Hz.
- Select 50 ms/div for the time-base.
- Decrease the generator´s output voltage to 50 mV (0 dB). This results in 2,5 div signal amplitude on the screen.
- Select AC trigger coupling.

REQUIREMENTS
- Check that there is no position of the LEVEL control that gives a triggered display.
- Increase the generator´s output voltage to 100 mV (+6 dB). This results in 5 div signal amplitude on the screen.
- Check that the LEVEL can be adjusted to a triggered display.

MEASURING RESULTS .....

D.8 SUBJECT — Horizontal expansion accuracy.

TEST EQUIPMENT — Time marker generator.

SETTINGS
- Apply a 100 us time marker signal to the Ch. A input socket.
- Press AUTO SET.
- Select 200 us/div for the time-base.
- Select a suitable input sensitivity with the Ch. A AMPL/DIV.
- Turn the X-EXPAND towards the UNCAL position 100 us/div.

REQUIREMENTS — Check for a display accuracy of + or - 5%.

MEASURING RESULTS .....

D.9 SUBJECT — Positioning range vertical and horizontal.

TEST EQUIPMENT — Constant amplitude sine wave generator.

SETTINGS
- Apply a 50 kHz/1,6 V (pp) sine wave to the Ch. A (B) input socket.
- Input impedance of Ch. A must be 50 ohm.
- Press AUTO SET.
- Select 200 mV/div input sensitivity for Ch. A (B).
- Adjust the generator output voltage to a vertical display of exactly 8 div.

REQUIREMENTS
- Turn the Ch. A (B) SHIFT clockwise and check that the sine wave does not cover the 5 div in the bottom half of the screen.
- Turn the Ch. A (B) SHIFT anti-clockwise and check that the sine wave does not cover the 5 div in the top half of the screen.

MEASURING RESULTS .....

SETTINGS
- Turn the Ch. A or B SHIFT so that the 8 div signal are exactly in the vertical mid of the screen.

REQUIREMENTS
- Turn the X-POSITION clockwise and check that the left 5 div of the screen are not covered by the signal.
- Turn the X-POSITION anti-clockwise and check that the right 5 div of the screen are not covered by the signal.

MEASURING RESULTS .....

E.	CURSORS	
E.1	SUBJECT	Voltage cursor accuracy.
	TEST EQUIPMENT	Square wave calibration generator.
	SETTINGS	- Apply a square wave voltage of 1 V (pp) to the Ch. A input. - Press AUTO SET. - Select 200 mV/div for Ch. A and AC input coupling. - Select 1 megaohm input impedance for Ch. A. - Press LOCK. - Press CURSOR. - Select cursors on REG A. - Position the 1st CURSOR in the horizontal mid of the top of the waveform. - Position the 2nd CURSOR in the horizontal mid of the bottom of the waveform.
	REQUIREMENTS	Check for a voltage cursor read-out of 1000 mV + or - 20 mV.
	MEASURING RESULTS	.....
E.2	SUBJECT	Time cursor accuracy.
	TEST EQUIPMENT	Time marker generator.
	SETTINGS	- Apply 1 ms time marker signal to the Ch. A input. - Press WRITE. - Press AUTO SET. - Select a suitable AMPL/DIV position for Ch. A. - Select 1 ms/div for the time-base. - Press LOCK. - Press CURSOR. - Select REG A. - Position the 1st CURSOR and the 2nd CURSOR so that they cover a distance of 8 time marker intervals.
	REQUIREMENTS	Check for a time cursor read-out of 8 ms + or - 0,0016 ms.
	MEASURING RESULTS	.....

F.	CALIBRATION VOLTAGE	
F.1	SUBJECT	Calibration voltage frequency accuracy.
	TEST EQUIPMENT	-
	SETTINGS	- Connect the CAL output voltage with the Ch. A input. - Press AUTO SET. - Press LOCK. - Press CURSOR. - Select cursors on REG A.
	REQUIREMENTS	Check by positioning of the cursors that the duration of one period of signal is 500 us (+or- 1,5 us). Check also the duration of both halves of a period are equal. This is important for the rms voltage measurement in section F.2.
	MEASURING RESULTS	.....
		- Select WRITE again.
F.2	SUBJECT	Calibration voltage accuracy.
	TEST EQUIPMENT	Digital multimeter and 50 ohm termination resistor.
	SETTINGS	Connect the multimeter (a.c. rms voltage range) between the instrument´s measuring earth and the CAL output socket and measure the rms value of the output voltage directly and with terminated (50 ohm) CAL output.
	REQUIREMENTS	Check for a voltage read out of 500 mV (+or- 5 mV) respectively of 250 mV (+or- 2,5 mV).
	MEASURING RESULTS	.....

G.	PLOT OUTPUT	
	SUBJECT	Accuracy of vertical and horizontal plot output voltages.
	TEST EQUIPMENT	Digital multimeter.
	SETTINGS	- Plug the plot cable into the DIN plot output socket at the rear side of the instrument. - Apply a the CAL signal to inputs A and B. - Press AUTO SET. - Position the two square wave signals in the vertical mid of the screen with SHIFT A and B. - Select 100 mV/div for channels A and B. - Select A versus B via the DISPLAY mode and switch on register RØ. - Select 200 ms/DT via the menus PLOT, SELECT and ANALOG. - Press SAVE/PLOT and then softkey ANALOG. The oscilloscope starts the plot action. This can be seen because the dot moves from left to right in the bottom of the screen.
	REQUIREMENTS	- Measure with the digital multimeter (d.c. voltage range) the maximum voltage at the vertical plot output (red banana plug, black is mass). This voltage must be 1000 mV + or - 30 mV. - Measure with the digital multimeter (d.c. voltage range) the maximum voltage at the horizontal plot output (blue banana plug, black is mass). This voltage must be 1000 mV + or - 30 mV.
	MEASURING RESULTS	.....

DISMANTLING THE INSTRUMENT

DISMANTLING THE INSTRUMENT

CONTENTS

5.0 Dismantling the instrument..... 5-1
5.1 General information..... 5-1
5.2 Removing the covers..... 5-1
5.3 Access to parts for the adjusting procedure..... 5-2

5.0 DISMANTLING THE INSTRUMENT

5.1 GENERAL INFORMATION

This section provides the dismantling procedures required for the removal of components during repair operations.
All circuit boards removed from the instrument must be adequately protected against damage, and all normal precautions regarding the use of tools must be observed.
During dismantling a careful note must be made of all disconnected leads so that they can be reconnected to their correct terminals during assembly.

CAUTION: Damage may result if:

- the instrument is switched on when a circuit board has been removed.
- a circuit board is removed within one minute after switching-off the instrument.

5.2 REMOVING THE COVERS

The instrument is protected by three covers: a front protection cover, a top cover and a bottom cover. To facilitate the removal of the instruments covers, first put the front protection cover in position.

Then proceed as follows:

- Hinge the carrying handle clear of the front protection cover.
- Stand the instrument on its protective front cover on a flat surface.
- Unscrew the screw marked E, which is placed in the center of the bottom cover (see figure 5.1).
- Unscrew the two screws A and B present in the left foot and the two screws C and D present in the right foot at the rear panel and remove these feet (see figure 5.1).
- The top cover and the bottom cover (without carrying handle) can be removed by shifting them backwards and lifting them of the instrument.

NOTE: When reinstalling the top and bottom covers again, take care that the wiring (coaxial cables and flat cables) is not damaged.
Re-installing the top and bottom covers has to be done in the reversed order as described above.

5.3 ACCESS TO PARTS FOR THE ADJUSTING PROCEDURE

After performing the actions which are described in section 5.2, all adjustment points are easily accessible.

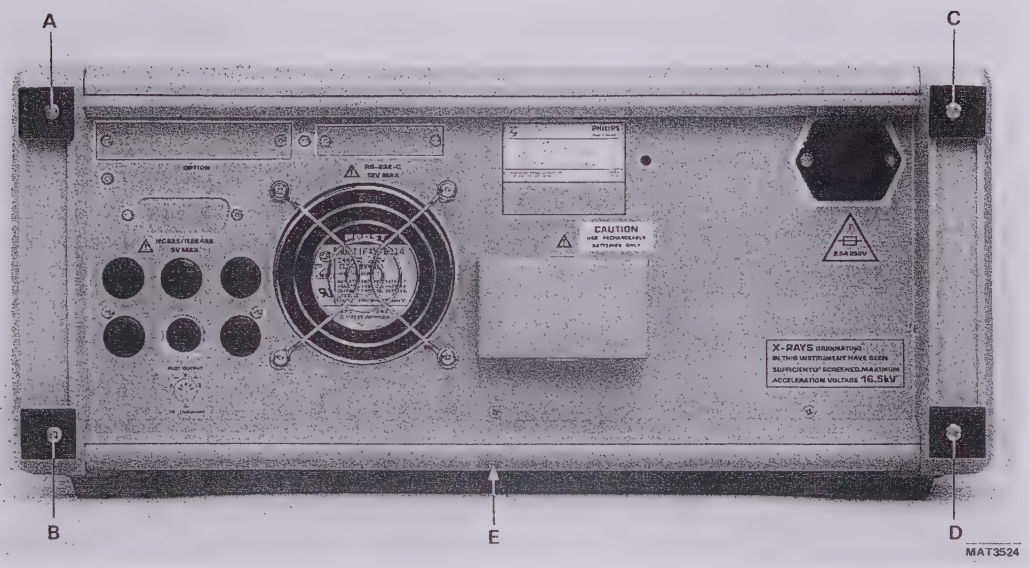

Figure 5.1 Removing the rear feet.

6.0 BLOCKDIAGRAM AND DESCRIPTION

This chapter serves to explain the main functions of the oscilloscope. The system can be divided into a number of sections:

- Acquisition section
- Calculation section
- Display and plot section
- Front section
- Control section
- Power supply section

6.1 ACQUISITION SECTION

By means of the acquisition section the analog signals are sampled and converted into digital codes.
Before conversion the analog input signals must be adapted so that an Analog to Digital Converter (ADC) is able to convert them.

6.1.1 The vertical channels (units A27...A32, A35)

The vertical section consists of two identical channels A and B with a sensitivity range of 5 mV/div...5 V/div in a 1-2-5 sequence.
Each channel includes a probe indication and an input protection circuit.

HF and LF attenuator and EXT trigger unit (units A27, A28, A29 and A30)

Since channel A and B attenuator units are identical, only channel A is described. The input signal is applied to the vertical input socket. From here the signal is split up into two components; namely:

- The HF (high frequency) component applied to the CAPACITIVE ATTENUATORS block, which gives signal attenuation of x100, x10 or x1,
- The LF and DC (low frequency and direct current) components applied to the COMPARATOR block. The OFFSET control signal, which comes from the MANAGEMENT UNIT via the OFFSET ADAPTION UNIT, is applied to the FEEDBACK RESISTORS block together with an offset bias level from the OFFSET BIAS circuit. The output of the FEEDBACK RESISTORS block is then applied to the COMPARATOR for vertical OFFSET control. In the input of the COMPARATOR, a d.c. blocking capacitor is present for the AC-coupled mode. This capacitor is short-circuited by a switch contact in the DC-coupled mode.

The output signals from the CAPACITIVE ATTENUATORS and from the COMPARATOR are added and amplified by the SUMMATION STAGE AND OUTPUT AMPLIFIER. The output signal is routed to the VERTICAL SIGNAL UNIT. A part of the output signal is fed back via the FEEDBACK RESISTORS block to the input of the COMPARATOR where it is compared with the LF and DC components in the input signal. Various feedback resistors can be selected in the FEEDBACK RESISTORS block. This occurs simultaneously with the selection of the attenuation coefficients of the CAPACITIVE ATTENUATORS.
The input impedance of the attenuator unit can be changed from 1 MOhm to 50 Ohm if the 50 Ohm termination resistor is switched on. If the dissipation in this resistor is excessive, the TEMPERATURE SENSING CIRCUIT gives an alarm to the microprocessor system. This alarm is routed via the line that is also used for the probe indicator to the PROBE DET. AND 50 OHM PROT. ADC on the MANAGEMENT UNIT.

The EXT TRIG circuit operates in the same way as the channel attenuators A and B. However, there are only two attenuation steps. The LINE trigger signal (LNTR), applied to the FEEDBACK RESISTORS block comes from the POWER SUPPLY. The selected output signal is applied to the TRIGGER SOURCE SELECTOR block.

The EVENTS/EXT CLOCK input circuit is identical to the EXT TRIG input circuit, except the EVENT LEVEL signal coming from the MANAGEMENT UNIT which determines the level on which the trigger is passing through. The output signal is applied to the EVENTS AMPLIFIER on the VERTICAL SIGNAL unit.

Vertical signal unit (unit A32)

The output of the summation stage of the HF ATTENUATOR UNIT is fed to the VAR ATTENUATOR-circuit via the PRE-AMPLIFIER which determines the attenuator factors x1, x2 and x5. The VAR-circuit is controlled by the VAR DAC which on its turn is controlled by the VAR frontpanel control via the data bus and the VAR-SHIFT LATCHES on the MANAGEMENT unit to achieve continuous control of the signal amplitude. Via the NORMAL-INVERT circuit the signal is routed to the BANDWIDTH LIMITER AND SHIFT-circuit. The SHIFT is controlled by the SHIFT DAC via the data bus and the VAR-SHIFT LATCHES on the MANAGEMENT unit.

The channel A as well as the channel B output signals are applied to the CHANNEL SWITCH.
This switch can be switched for single channel A, single channel B, dual channel or add. In add the added signal is present on the channel A output.

The setting of the channels is realized via the microprocessor system and the MANAGEMENT unit. The microprocessor system is able to react on changes on the frontpanel or on selection of softkey functions by the operator of the instrument.

Management unit (unit A25)

The settings of the vertical channels A, B, EXT TRIG and EVENTS/ EXT CLOCK input and also the VERTICAL SIGNAL UNIT are controlled by the microprocessor system via the ATT. - VERTICAL SIGNAL AND TRIGGER LATCHES block on the MANAGEMENT UNIT.
On this unit the digital control codes from the microprocessor system are converted into analog values by the Digital to Analog Converters (DAC): TRIGGER LEVEL, OFFSET A (B), EVENT LEVEL.
The VAR-SHIFT DACs are driven, via the VAR-SHIFT LATCHES.
The analog 50 Ohm and probe detection signals are converted into a digital code by the PROBE DETECTION AND 50 OHM PROT. ADC circuit and can be read by the microprocessor system.
DATA and ADDRESS BUFFERS are also present on this unit to buffer the data and control signals for the DACs, ADCs and several latches.
A number of control signals is generated by the ADDRESS DECODER.

A SERIAL-PARALLEL CONVERTER circuit converts the serial data from the DELTA-t CIRCUIT on the clock unit into parallel data, which is applied to the microprocessor system when an IL$\emptyset$6--LT interrupt signal is generated.
Communication between the CCD logic and the microprocessor system is possible via an INPUT LATCH and an OUTPUT LATCH.

6.1.2 The signal switches and the peak detectors (unit A33)

The CHANNEL SWITCH output signals are each applied to a SIGNAL SWITCH which is controlled by an OUTPUT LATCH and by the ACQUISITION CONTROL LOGIC via the STATUS LOGIC.
Depending on the selection of the MIN / MAX softkey function, signals are fed through PEAK DETECTORS or not. Resetting of the PEAK DETECTORS is done in a rate which depends on the time base speed.

6.1.3 The P^2CCD circuits and control logic (unit A33 and A26)

Signals from the signal switches are passing P^2CCD circuits. These profiled peristaltic charged coupled devices acts as analog shiftregisters which are able to store signal samples with a rate which depends on the selected time base speed. This rate is generated by the FAST TIME BASE DIVIDER and via DRIVERS applied to the P^2CCD circuits. For time base speeds which can not be handled by the ADC anymore, the P^2CCD devices are used for time conversions. This means that signal samples can be taken by the P^2CCD circuits with a rate of up to 500 Mega-samples/second and later converted by an ADC circuit with a lower rate of 200 kHz per channel. This lower rhythm is generated by the SLOW CLOCK DIVIDER.
Each channel contains a P^2CCD device which contains two sections of 256 signal samples. So in each channel 512 signal samples can be present.

The output signals of the P^2CCDs are applied to fast CLAMP / INTEGRATE / HOLD circuits. These CIH circuits are able to hold the signal information for a time which is long enough for the TRACK AND HOLD circuit behind them to take them over.
The holded signal levels are applied to a P^2CCD CHANNEL SWITCH and to differential stages, whose outputs also are applied to the P^2CCD CHANNEL SWITCH. The P^2CCD CHANNEL SWITCH switches in a way which depends on the selected time base modes under the control of the P^2CCD OUTPUT LOGIC.
This logic also generates a start conversion signal for the ADC, which is also a clock signal for the SHIFT REGISTER in the ACQUISITION CONTROL LOGIC.
This switch places the output signal samples in serial and transportsthem to the TRACK AND HOLD circuit on unit A11.

The P^2CCD system is controlled by a CCD LOGIC which delivers control signals and which controls the FAST TIME BASE DIVIDER which produces the clock signals for the P^2CCD devices. The logic is controlled by trigger signals, and by the ACQUISITION CONTROL LOGIC. This ACQUISITION CONTROL LOGIC handles the timing in the different time base modes.
The CCD LOGIC also controls the PEAK DETECTOR RESET LOGIC which generates the reset pulses for the PEAK DETECTORS.

Aliasing (f sampling < 2x f trigger) is detected by an ALIASING DETECTOR of which the output signal is applied to the microprocessor system via an INPUT LATCH to control the frontpanel ALIASED lamp.

Auto triggering can be selected by the microprocessor system via the OUTPUT LATCH. The AUTO TRIGGER LOGIC receives the trigger pulses from the CCD LOGIC and produces an auto trigger for this CCD LOGIC when during a time of 100 ms no trigger signal appears. The NOT TRIG´D frontpanel lamp is controlled via the INPUT LATCH and the microprocessor system.

The TRIGGER DELAY COUNTER is a down counter of which the loading is effected by the microprocessor system with a value derived from the softkey settings in combination with he TIME/DIV switch setting. Upon the receipt of a trigger pulse from the CCD LOGIC the TRIGGER DELAY COUNTER starts counting time base output pulses until its zero state is reached.
This effects in a pulse which stops the sampling of new input signal samples by the P^2CCD devices. The P^2CCD contents can now be corrected, converted, stored in TRACE REGISTER RØ and displayed on the CRT screen.

6.1.4 The ADC circuit (unit A11)

The signal from the P^2CCD CHANNEL SWITCH is applied to a CORRECTION CIRCUIT, to correct some non-linearity of the P^2CCDs. The output signal is applied to a TRACK AND HOLD circuit which is able to hold the levels for a time long enough for the ADC circuit behind it to do the conversion to a 12-bit digital word. The ADC is able to perform conversion with a maximum speed of 400 kHz and is controlled by the ADC LOGIC. The 12-bit digital code is converted from straight binary into two´s complement by the CODE CONVERT circuit and then latched in the SAMPLE DATA LATCH for further data handling by the Digital Processing Unit (DPU).
The ADC output is also connected to an OVERFLOW DETECTION circuit, which on its turn is connected with the DPU.

6.1.5 The trigger, trigger events and trigger delay circuits (unit A26, A31 and A32)

A trigger signal can be derived via the TRIGGER SOURCE SELECTOR circuit from one of the sources channel A, channel B, the EXT TRIG input socket or the LINE frequency. The selected trigger signal is via softkey selectable TRIGGER FILTERS and a TRIGGER AMPLIFIER with trigger slope selection applied to an AUTO P-P LEVEL DETECTOR circuit where it is influenced by a signal derived from the frontpanel TRIGGER LEVEL control via the TRIGGER LEVEL DAC. It also delivers the DC level of the input signal to an AUTO OFFSET ADC, which converts this into a digital code for the microprocessor system, which is used for AUTO OFFSET.
The trigger signal is then applied to a TRIGGER AMPLIFIER + TV SYNC SEPARATOR where it can pass a tv. sync. separator, if selected. Next the TRIGGER LOGIC generates trigger pulses from the trigger signal. These trigger pulses go to the TRIGGER SYNC LOGIC on unit A49.

Signals from the EVENTS AMPLIFIER on the VERTICAL SIGNAL UNIT are applied to an EVENTS COUNTER which can be preset by a value which is generated by the microprocessor system depending on the number of events selected by the user.

The trigger signal from the TRIGGER LOGIC as well as the output signal from the EVENTS COUNTER are fed to the TRIGGER SYNC LOGIC.

6.1.6 The delta-t and digital time base circuits (units A26, A34, A48)

A DELTA-t CIRCUIT is introduced to measure the time between the moment of triggering and the real sample moment. This is needed to know for the different modes, on which memory location, converted digital codes have to be stored.
The DELTA-t CIRCUIT consists of a DIGITAL TO ANALOG CONVERTER, an INTEGRATOR and an ANALOG TO DIGITAL CONVERTER.
The input voltage for the INTEGRATOR is determined by themicroprocessor system and via the DAC applied to the INTEGRATOR.
The INTEGRATOR is started on a trigger from the TRIGGER SYNC LOGIC and is stopped when the first sample is taken. The output voltage of the INTEGRATOR, which is a measure for the time between the trigger pulse and the sample pulse, is converted via A SERIAL PARALLEL CONVERTER circuit into parallel data. These are applied to the microprocessor system via DATA BUFFERS after an ILØ6--LT interrupt signal is generated.

A 100 MHz OSCILLATOR and a 125 MHz OSCILLATOR, which are controlled by the microprocessor system applies a signal to the FREQUENCY DOUBLER on unit A48.
The output signal (FAST CLOCK) can be divided by the FAST TIME BASE DIVIDER by different factors. These factors depend on the selected time base speed. The dividers are set for a certain factor via the microprocessor system. The selected frequency depends on the selected time base position.

A SLOW CLOCK GENERATOR and a SLOW CLOCK DIVIDER generate a slow clock signal for the slow time base settings.

The ADDRESS DECODER and the CONTROL LATCH enable the microprocessor system to have control the over time base circuits.

6.1.7 The acquisition control logic (units A5 and A9)

The ACQUISITION CONTROL LOGIC controls the timing of the acquisition section in all the different time base modes.

The circuit is operating in a different way for each of the four time-base modes ROLL - DIRECT - P^2CCD and RANDOM SAMPLING.

The ACQUISITION CONTROL LOGIC is informed about the mode by the microprocessor system via the MODE REGISTER.
This MODE REGISTER also controls the SLOW TIME BASE LOGIC and the SHIFT LOGIC.
The SLOW TIME BASE LOGIC generates various control signals for the various time base settings in the ROLL and DIRECT modes.
The SHIFT LOGIC keeps track of wether samples that are taken are still in the P^2CCD or are leaving it and informs the DPU CONTROL via the STATUS MUX.

6.2 THE CALCULATION SECTION (units A8 and A9)

The calculation section consists of a Data Processing Unit (DPU unit A9) which is a very fast microcomputer system with a cycle time of 125 nsec.
It takes data from the ADC, performs calculations on it and sends the data to the TRACE DATA LATCH. All data is transported via the BUFFER.

The possible calculations are:

- digital MIN / MAX function in the ROLL and the DIRECT mode
- zero channel substraction in the P^2CCD mode
- averaging
- interpolation in the P^2CCD and the RANDOM SAMPLING mode
- overflow detection

To perform the calculations the DPU has a number of calculation registers and function blocks:

- REGISTER I, II and III
- SHIFT REGISTER
- +/- (complement function)
- ADDER
- LIMIT DETECTION

An overflow at the ADC is detected by the OVERFLOW DETECTION circuit, which enables the REFLECTION SUPPRESSION.

The DPU has registers in which data are stored. These are:

- PRE-TRIGGER RAM.
  This is used as a shift register and contains pre-trigger data in the DIRECT mode.
  It is also used as work space for the digital MIN / MAX calculations.
- AVERAGE RAM.
  Used for average calculations.
- FLAG RAM.
  In this ram is stored wether samples are real samples or samples obtained by interpolation. If an ovwerflow occurs, this is also stored by means of a flag. Flags are stored by means of the FLAG HANDLER.

The DPU is controlled by the DPU control (unit A8). The heart of the DPU control is the CONTROL MEMORY. This serves as a program memory for the DPU.
This memory is loaded for the various functions by the microprocessor system via the ADDRESS MULTIPLEXER and the BUFFER.
The DPU control has a PIPELINE REGISTER, which holds the current instruction, while the next instruction is fetched from the CONTROL MEMORY.
The instruction which is fetched depends on the address given by the ADDRESS MULTIPLEXER.
This address depends on data given by the STATUS MULTIPLEXER, which on its turn gets status signals from various function blocks.
The PIPELINE REGISTER is controlled by the START/STOP logic and the CONTROL LATCH.
When a DPU program is finished, the START/STOP LOGIC informs the microprocessor system about this via interrupt line ILØ2--LT.
The INSTRUCTION REGISTER and the CONTROL REGISTER, control theoperation of the DPU control.
The ADDRESS GENERATOR generates addresses for the PRE TRIGGER RAM, the AVERAGE RAM and the FLAG RAM.
The ADDRESS GENERATOR consists of an ADDRESS REGISTER and a PRETRIGGER COUNTER, which can be loaded via a buffer. The MULTIPLEXER selects the ADDRESS from the PRETRIGGER COUNTER or from the ADDER. The ADDER adds the addresses from the ADDRESS REGISTER and the OFFSET JUMP REGISTER. The latter enables the DPU to make jumps in program execution.
In the DIRECT MODE, the TRIGGER ADDRESS COMPARATOR generates a signal when all available pretrigger samples have been transported to the TRACE MEMORY.
The ADDRESS DECODER enables the microprocessor system to have control over the calculation section.

6.3 DISPLAY AND PLOT SECTION (units A1, A2, A3 and A4)

The display section consists of hardware to display trace data as well as text data on the C.R.T display.
A complete display cycle for all traces and all texts to be displayed, is realized in less than 20 ms. This results in a stable and flicker-free display.

Trace data words from the DPU system which have to be copied to the TRACE MEMORY in the display section are latched in the TRACE DATA LATCH with the rate of the DPU clock and the display section is for each new trace data word informed via the HANDSHAKE LOGIC (signal sample ready) that it is available for storage in REGISTER RØ of the TRACE MEMORY.
Addresses for the TRACE MEMORY are then generated by the COPY ADDRESS COUNTER. This counter which is directed to the TRACE MEMORY via ADDRESS MULTIPLEXER II starts each new copy cycle for a complete new trace with the generation of address zero. It counts then with the same rate as the DPU. After the storage of each trace data word in the TRACE MEMORY, a sample ready acknowledge signal is given to the DPU via the HANDSHAKE LOGIC.

6.3.1 The save function

When a SAVE function is selected, the contents of REGISTER RØ is copied in one or more of the REGISTERS R1, R2 or R3.
The trace data words are then first saved in the SAVE LATCH before they are saved in the selected REGISTER.
The REGISTER can be addressed then by the DISPLAY ADDRESS COUNTER via ADDRESS MULTIPLEXERS I AND II.

6.3.2 Trace display

X=t display mode

The trace data words to be displayed are transferred from the TRACE MEMORY via the DISPLAY CONTROL LATCH to an INVERT stage which offers the facility to invert the stored data before display. This facility can be softkey selected per register.
Data passes then a VERTICAL EXPAND stage of which the expand factor is set in combination with the gain factor of the Y AMPLIFIER later in the signal path. In this way, the Y/5, Y*1 and Y*5 vertical expand modes are realized.
The resulting data is latched in a LATCH and vertical position information, which is calculated by the microprocessor and applied via a VERTICAL POSITION LATCH, can be added by a VERTICAL POSITION ADDER stage. It is then converted from 2´s complement into straight binary by the CODE CONVERT circuit and latched in a YDAC LATCH before the conversion by the digital to analog converter YDAC. The converter output signal can then be deglitched by a SAMPLE AND HOLD circuit and influenced by a DOT JOIN/SMOOTH circuit. It is then amplified by a Y AMPLIFIER by a factor which depends on the selected vertical expand factor. The signal is then applied to a Y FINAL AMPLIFIER which directly drives the vertical deflection plates of the C.R.T.

Horizontal deflection signals are derived from the addresses for the TRACE MEMORY, which are generated by the DISPLAY ADDRESS COUNTER. These addresses are applied via the DISPLAY ADDRESS DATA BUFFFER to the HORIZONTAL EXPAND I CIRCUIT.
Horizontal expand factors of *1, *2, *4 and *8 can be realized. After expansion, horizontal position information, which is calculated by the microprocessor system and applied via a HORIZONTAL POSITION LATCH, can be added by a HORIZONTAL POSITION ADDER stage.
An additional expand factor of *1 or *8 can be realized in the HORIZONTAL EXPAND II circuit before the conversion by the digital to analog converter XDAC.
The converter output signal can then be deglitched by a SAMPLE AND HOLD circuit and influenced by a DOT JOIN/SMOOTH circuit. It is then amplified by an X AMPLIFIER of which the gain factor depends on the setting of the continuous X-EXPAND control on the frontpanel. This information is applied via an X-EXPAND LATCH and an X-EXPAND DAC to the X-AMPLIFIER.
The signal is then applied to an X FINAL AMPLIFIER which directly drives the horizontal deflection plates of the C.R.T.

A versus B display mode

This display mode is only selectable in dual channel mode.
The channel B TRACE MEMORY contents is applied to the vertical deflection plates of the CRT in a way as described for the X=t display.

For horizontal deflection the channel A TRACE MEMORY contents is used instead of the addresses from the DISPLAY ADDRESS COUNTER. The channel A trace data is converted from 2's complement into straight binary via the CODE CONVERT circuit and then transferred via the AVSB DATA BUFFER to the horizontal signal path and the horizontal deflection plates as described before for the X=t display addresses.

6.3.3 Text display

The text which has to be displayed, is generated by the microprocessor system and stored in the TEXT MEMORY.
Data is transferred from the microprocessor data bus via the DATA/TEXT BIDIRECTIONAL LATCH to the TEXT MEMORY.
Addresses from the microprocessor address bus are applied to the TEXT MEMORY via ADDRESS MULTIPLEXER I.

Each dot to be displayed on the C.R.T screen is stored in the TEXT MEMORY by a word consisting of a vertical and a horizontal coordinate and an intensity flag.

There are a number of different text blocks like:

Top area text	(TAT)
Trace area text	(TRAT)
Bottom area text	(BAT)
Softkey text	(SKT)
Miscellaneous text	(MSC)

The vertical coordinates are applied to the vertical deflection plates of the C.R.T. via a TEXT/TRACE BIDIRECTIONAL BUFFER and in a way as described for the X=t display.

The horizontal coordinates are applied via the LINE TEXT DATA BUFFER (for TAT, TRAT and BAT) or via the SOFTKEY TEXT DATA BUFFER (for SKT) or via the AVSB DATA BUFFER (for MSC) to the horizontal signal path and the horizontal deflection plates as described before for the X=t display addresses.

The intensity flag is used to inform the Z-stage about normal or intensified display.

6.3.4 Display control

Each display cycle, which consists of a fixed sequence of trace data blocks followed by a fixed sequence of text blocks, is controlled by the microprocessor system.
The microprocessor system places via a DATA BUFFER preset and control data into a number of OUTPUT PORTS, an Z + INTERRUPT TIMER and a PRESET REGISTER for the DISPLAY ADDRESS COUNTER, at the start of the display of each display data block.

At the same moment new position information is placed in the VERTICAL POSITION LATCH and in the HORIZONTAL POSITION LATCH.

At the end of each display block an interrupt signal ILØ5--LT is generated which is applied to the microprocessor system to ask for the actual preset and control data for the next display block.

6.3.5 Z-control (unit A1 and A15)

The Z-AMPLIFIER is controlled by the following circuits:

- Reflection detection circuit
- Overscan detection circuit
- Z detection circuit

Reflection detection

Reflection is caused by adding a position information to a signal information in the vertical as well as in the horizontal signal path which causes an overflow in the highest (non-existing) bits. Such an overflow causes the top of the signal being displayed at the bottom of the display like it is a reflection. In a similar way an underflow causes a reflection in the top of the display. Both situations can also occur in horizontal direction. These reflection can be detected by the REFLECTION DETECTION circuit and via the Z-DETECTION circuit suppressed by the Z-AMPLIFIER.

Overscan detection

Signals have to be displayed within the trace area of 8x10 divisions of the C.R.T. screen. Overscan in one of the four screen area directions is detected by the OVERSCAN DETECTION circuit and suppressed by the Z-AMPLIFIER.

Z-detection

Via the Z-DETECTION which is controlled by the Z-TIMER circuit the trace will be blanked when no traces or texts have to be displayed. The text can also be intensified if required. The last, for example, for active functions.
The Z-DETECTION output signal is applied to the Z-AMPLIFIER where it is influenced by the INTENSITY controls for the trace as well as for the text. The resulting signal is applied via the final Z-AMPLIFIER to the Wehnelt Cylinder of the CRT thus controlling the intensity of the trace on the screen. The focussing of the trace is controlled via the FOCUS block, under the influence of a FOCUS control by a signal which is applied to the focus grid of the CRT.

The a.c. and d.c. components of the output blanking signal from the Z-AMPLIFIER are guided along different paths.
The a.c. path runs straight to the FINAL Z-AMPLIFIER via a high voltage capacitor.
The d.c. component is modulated with 200 kHz by a MODULATOR, guided via a high voltage capacitor to the high voltage part and demodulated again by a DEMODULATOR. The resulting components are added and applied to the FINAL Z-AMPLIFIER and from there to the Wehnelt cylinder of the C.R.T.

6.3.6 Plot-output (unit A1)

Once per cycle of 20 ms a value can be plotted via the ANALOG PLOT INTERFACE. The X and Y informations are derived from the FINAL AMPLIFIERS and the penlift control is realized via the Z-AMPLIFIER stage.

6.3.7 Option handling

For OPTION handling the TRACE MEMORY as well as the TEXT MEMORY can be addressed via the microprocessor system address bus.

The data flows from the microprocessor system data bus to or from the TRACE MEMORY and the TEXT MEMORY is realized via the DATA/TEXT and TEXT/TRACE BIDIRECTIONAL latches.

6.3.8 Calibrator (unit A1)

A CALIBRATOR generator generates a 1 Vp-p 2 kHz calibration signal for the user which can be used to check the calibration of the system.

6.4 FRONT SECTION (units A13 and A14)

The front section contains a number of softswitches (the softkeys beside the CRT inclusive) and rotary controls (optical switches) of which the settings are read by the microprocessor system.

The softswitches are placed in a SOFT SWITCH MATRIX which places a row of switch settings in the FRONT SWITCH BUFFER each time that the matrix is addressed by the microprocessor system. The complete matrix is scanned every 40 ms.

The optical switches generate interrupt signals IL$\emptyset$3--LT for the microprocessor system when they are operated by the user and the microprocessor in turn addresses the circuit after which the information (from the ROTARY ENCODER) about the direction of rotation is placed on the data bus for interpretation by the microprocessor system.

The front section also contains a number of front panel leds which are controlled by the microprocessor system via LED DRIVERS.

The addresses which are generated by the microprocessor system, are decoded by a number of ADDRESS DECODERS.

6.5 CONTROL SECTION (units A5 and A6)

The control section consists mainly of a powerfull MICROPROCESSOR system configuration, with an 68000 uP, a RAM MEMORY for data and a ROM MEMORY containing the system software. The MICROPROCESSOR is running at a frequency of 8 MHz which is provided by a CLOCK GENERATOR which is driven by a 16 MHz OSCILLATOR.

An ADDRESS DECODER decodes a number of addresses resulting in a number of I/O SELECT signals for the various units and a number of MEMORY SELECT signals for the various memories via the I/O and MEMORY SELECT BUFFERS.

Interrupt signals from various units are applied to an INTERRUPT PRIORITY LEVEL DECODER. From here the interrupt with the highest priority is send to the MICROPROCESSOR.

A WATCHDOG circuit detects abnormal program sequences via an OUTPUT PORT and resets the MICROPROCESSOR via the RESET/HALT block in order to restart the program. This is done by a monostable flip flop.

A BUS ARBITER controls the system bus and can give the control over the bus to processors which are fitted on options, if they ask for bus control via their BUS REQUEST signals.

The battery voltage is compared with a reference voltage by a COMPARATOR. The battery status as well as the settings of the on board SERVICE switches are applied via an INPUT PORT to the microprocessor system.
A too low battery voltage results via a SUPPLY VOLTAGE SWITCH in the saving of the memory contents.

The following functions are performed by this control section:

- Front panel settings are read and processed.
- Front panel leds are controlled.
- Time base, trigger delay counter, events counter and acquisition control logic circuits are set in accordance to the user selected settings.
- Digital processing circuits are provided with a separate programm which depends on on the selected functions.
- The display system for trace, text and analog plot out data is controlled.
- If an option is installed, the complete handling is controlled.

6.7 THE ACQUISITION SYSTEM

6.7.1 Introduction

Below is a brief explanation of the principle of the acquisition system. See also figure 6.5.

It is assumed that:

- The oscilloscope is in recurrent mode (except roll mode)
- The oscilloscope is in single channel mode
- Average is off
- MIN/MAX is off
- Trigger delay by events is deselected

It is recommended to read this section together with the sections 8.5.3, 8.8.2 and 8.26.2.

6.7.2 Roll mode

After a new time base setting counter 3 in the slow time base logic (D1801 on unit A5) counts down the P^2CCD length, to enable the P^2CCD to be filled with good samples. Next ENSWTB goes high and the acquisition can start.
The P^2CCD takes continuously samples with a rate of 400 kHz, which appear 256 transport clocks later at the output, after which they are corrected (analog zero correction) and converted by the ADC. The DPU takes only a sample if it comes together with a TKSA pulse. The repetition rate of this pulse depends on the time base setting.
The samples are placed in the pretrigger ram of the DPU which contains the data for a full trace.
These data are shifted through when a sample is taken, to obtain the roll effect.
Each time the display section generates a SYDP, a full sweep of trace data are transported to the display ram in one stroke, to avoid discontinuities in the trace.

6.7.3 Direct mode

After a time base setting counter 3 in the slow time base logic (D1801 on unit A5) counts down the P^2CCD length, to enable the P^2CCD to be filled with good samples. Next ENSWTB goes high and the acquisition can start.
First the DPU loaded and started by the microprocessor. Next the DPU generates TRRY to the A.C.L., which on its turn generates TDLD--LT to load the trigger delay counter. Next HDOF goes low and the system waits for the first incoming trigger pulse.
At the arrival of a trigger pulse, the trigger delay counter starts counting down at the frequency of SYSWTB, which is determined by the time base setting.
The trigger delay counter generates TDUF when it has counted down to zero. If the trigger delay setting was zero divisions, the trigger delay counter was preset to zero.

TDUF causes the A.C.L. to generate DAVA 256 transport clocks later, which enable the samples to shift through the P^{2}CCD. The samples are corrected (analog zero correction) and converted by the ADC.
When DAVA is high, the DPU takes the samples only if they come together with a TKSA pulse.
The repetition rate of TKSA depends on the time base setting.
The samples are stored in the pretrigger ram.
Transport of samples to the display section happens asynchronously.
As soon as a sample is ready for transport to the display section and the trace data latch is released, the sample is placed in the trace data latch.
When a complete sweep of 4096 samples is processed in this way, an interrupt is generated to the microprocessor and the DPU stops. Next the microprocessor restarts the DPU, which on its turn generates TRRY, and so on.
When pretrigger is selected, TRRY is delayed which enables the DPU to take samples to get the desired pretrigger samples, which are stored in the pretrigger ram. After a trigger and DAVA as many samples are taken,that together with the available pretrigger samples, a full sweep of 4096 samples is made.

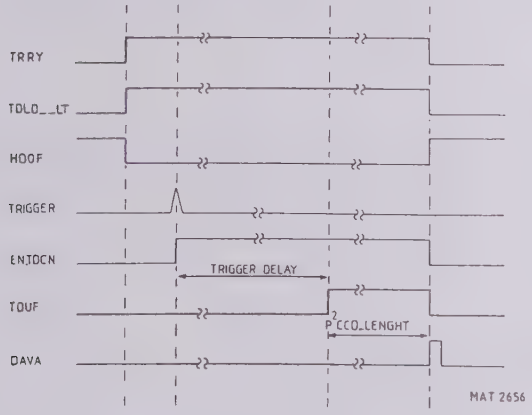

Figure 6.3 Basical timing diagram - Direct mode.

6.7.4 P^{2}CCD mode

In this mode the time conversion principle is used.
After a new time base setting, the P^{2}CCD starts taking samples, with a rate that is determined by the sample clock. The frequency of the latter depends on the time base setting, but is much higher than in the direct mode.
The DPU is loaded and started by the microprocessor. Meanwhile the P^{2}CCD is already filled with samples.
Next the DPU generates TRRY to the A.C.L., which on its turn generates TDLD--LT to load the trigger delay counter. Next HDOF goes low and the trigger delay counter waits for the first incoming trigger pulse.

The P^2CCD contains all pretrigger samples. At the arrival of a trigger pulse, the trigger delay counter starts counting down at the frequency of the sample clock, which is equal to the frequency of the transport clock. The trigger delay counter generates TDUF when it has counted down to zero. If the trigger delay setting was zero divisions, the trigger delay counter was preset to 512, which is equal to the P^2CCD length. In case of a pretrigger selection of 10 divisions, the trigger delay counter is preset to zero.
As TDUF is generated, the P^2CCD contains all samples for the complete sweep, so the taking of samples is stopped. TDUF also causes the CCD logic to change the transport clock frequency to 100 kHz and to make CDRD high.
Also DAVA goes high and the DPU takes all uncorrected and converted samples from the ADC and places them in the pretrigger ram.
When this is done, the A.C.L. generates RSSW and ZECH, which presets the trigger delay counter again. Next the P^2CCD reads zero voltage samples with the fast sampling clock, determined by the time base setting. As TDUF is generated the A.C.L. generates STSW, which causes the CCD logic to make CDRD high. Now 512 zero voltage samples are taken by the DPU and substracted from the corresponding samples in the pretrigger ram (digital leakage correction). Next the DPU calculates all interpolated samples. When the whole sweep is ready, the trace data are transported in one stroke to the display section, thereby ignoring the SYDP signal.
At last an interrupt is generated to the microprocessor and the DPU stops. Next the microprocessor restarts the DPU; which on its turn generates TRRY and so on.

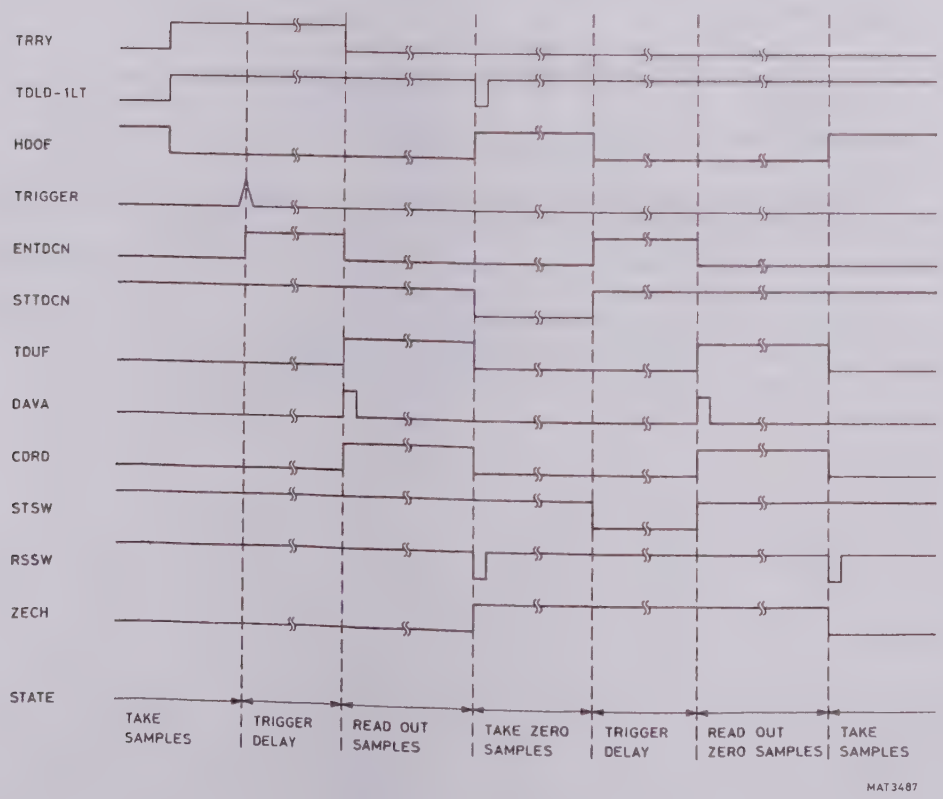

Figure 6.4 Basical timing diagram - P^2CCD mode.

6.7.5 Random sampling mode

The random sampling mode operates roughly in the same way as the P^2CCD mode.

The main differences are:

- The sampling frequency is independent of the time base setting (50 MHz).
- The number of samples that is read in every stroke depends on the time base setting.
- The trigger delay counter is preset in such a way that the samples used at every read out stroke are almost at the output of the P^2CCD as TDUF is generated.

The time that passes by to let the samples shift to the output is used to inform the DPU about the result of the delta-t measurement (the time difference between the trigger pulse and the first sample pulse). The DPU uses this to place the samples in the correct locations in the pretrigger ram.
When the zero voltage samples are processed, a new sweep of samples with probably a different delta-t result is done and so on.
Once in every display cycle (20 ms) SYDP goes high.
Then the DPU calculates interpolated samples and transports the trace data, which is probably not a complete sweep, in one stroke to the display section.
In this way as many as possible sweeps can be done, for the fastest time base setting only 2 or 3 samples are taken every sweep.

When a transport of trace data to the display section is finished, an interrupt is generated to the microprocessor and the DPU stops. As in the other modes, the microprocessor restarts the DPU to start the whole cycle again.

6.7.6 Miscellaneous

- The special modes are combinations of the direct mode and the P^2CCD mode.
- Maximum resolution mode is a combination of P^2CCD mode and random sampling mode.
- In single scan mode the microprocessor checks the sample flags in the display ram to determine if a scan is complete.
- In dual channel mode, the signal CHPT (channel pointer) informs the DPU from which channel the samples are.
- In MIN/MAX mode the signal MMPT informs the DPU if the samples come from the min or from the max peak detector.
- The average function is completely performed in the DPU.

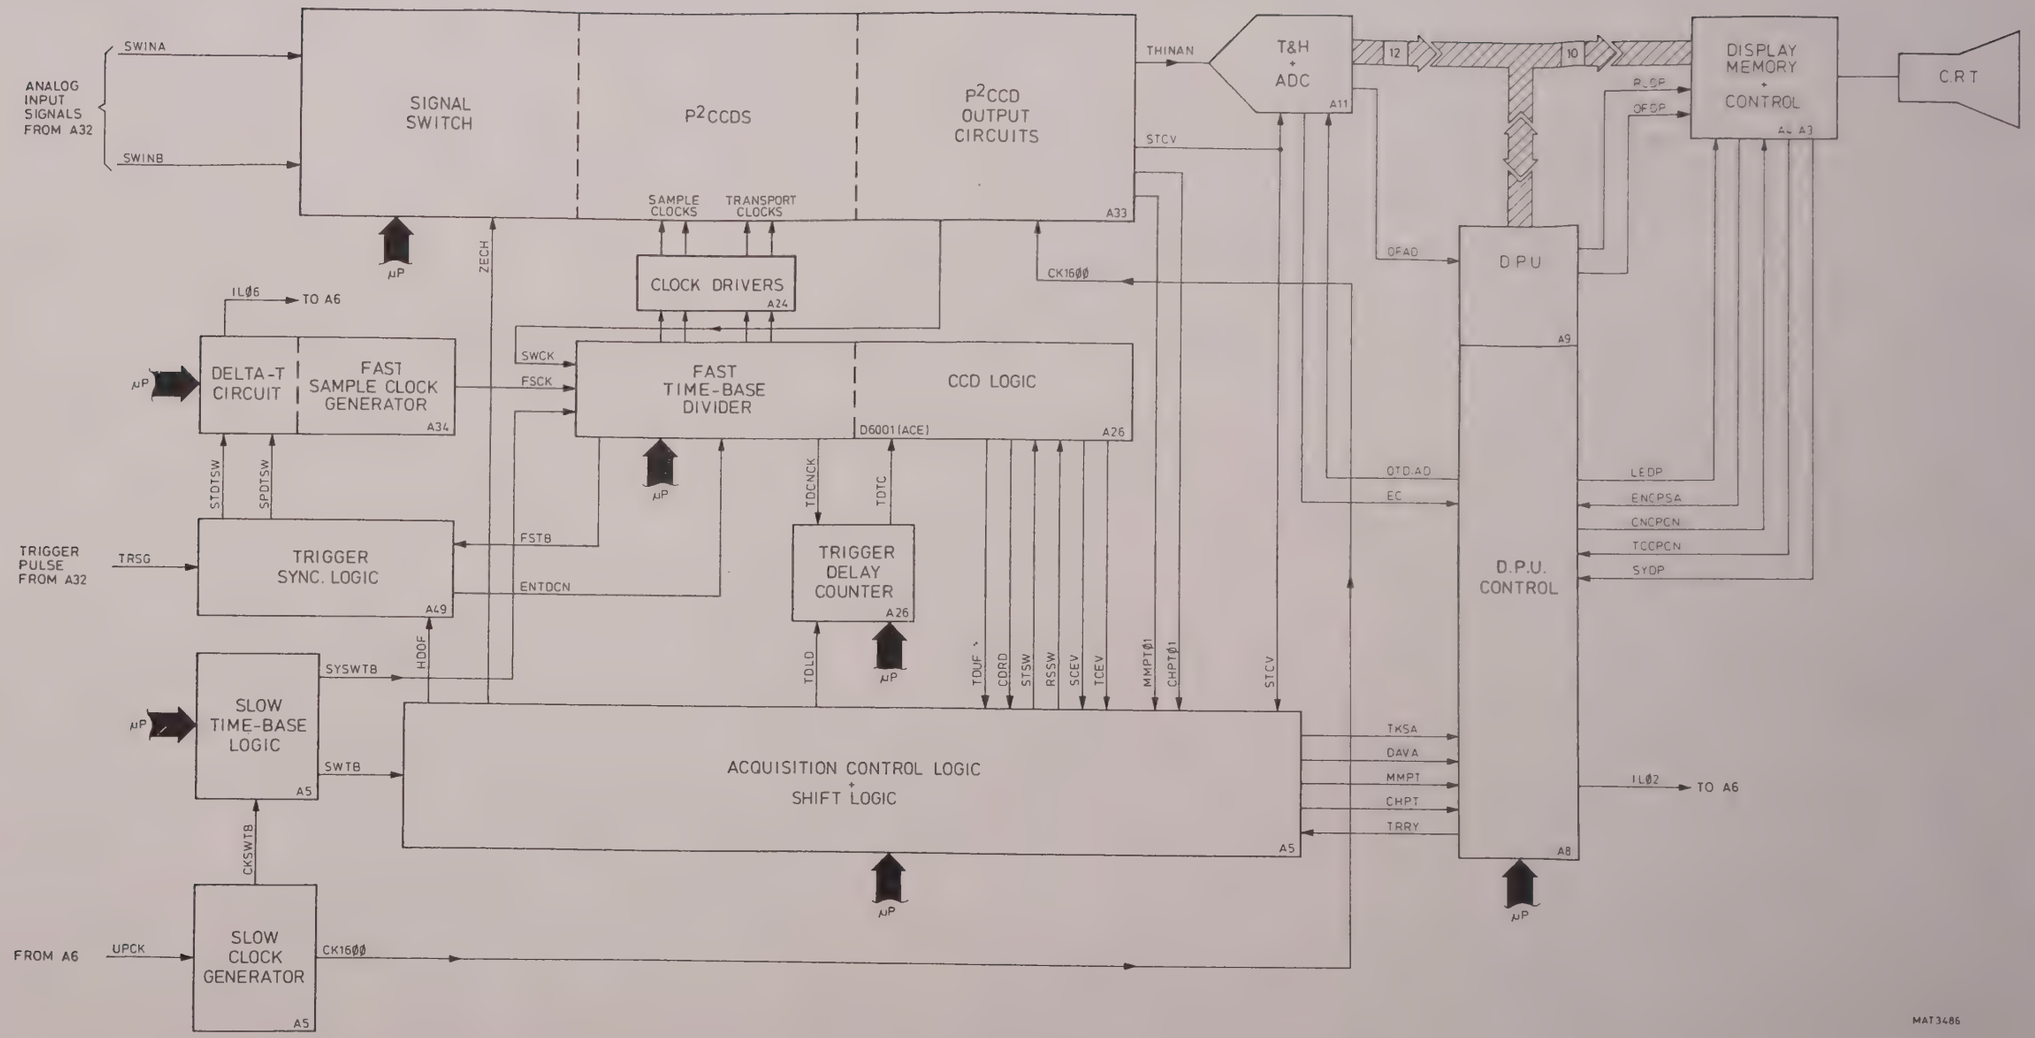

Figure 6.5 Blockdiagram of the acquisition system.

6.7.7 Survey of clock signals.

Mode	Time-base range	Sample clock	Transport clock	Slow time-base
Roll Single Normal	360 s/div : 50 ms/div	400 kHz : 400 kHz	400 kHz : 400 kHz	1,111 Hz : 8 kHz
Roll Dual Normal	360 s/div : 50 ms/div	200 kHz : 200 kHz	400 kHz : 400 kHz	0,555 Hz : 4 kHz
Roll Single Min/max	360 s/div : 50 ms/div	200 kHz : 200 kHz	400 kHz : 400 kHz	1,111 Hz : 8 kHz
Roll Dual Min/max	360 s/div : 50 ms/div	200 kHz : 200 kHz	400 kHz : 400 kHz	0,555 Hz : 4 kHz
Direct Single Normal	5 s/div : 1 ms/div	400 kHz : 400 kHz	400 kHz : 400 kHz	80 Hz : 400 kHz

INTRODUCTION TO CIRCUIT DESCRIPTIONS 7

INTRODUCTION TO CIRCUIT DESCRIPTIONS

CONTENTS

7.0 Introduction to circuit descriptions..... 7-1
7.1 General..... 7-1
7.2 Explanation of signal name set up..... 7-1
7.2.1 Signal names..... 7-1
7.2.2 Signal name list..... 7-2

7.0 INTRODUCTION TO CIRCUIT DESCRIPTIONS

7.1 GENERAL

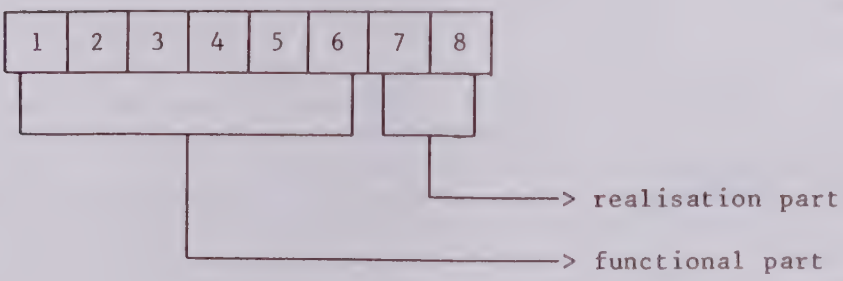
The functioning of the circuits is explained in chapter 8.0 "CIRCUIT DESCRIPTION" per unit in the sequence of the unit numbers (A ..). Every unit section contains the circuit description, the lay-out of the p.c.b., the circuit diagram(s) and a signal-name list, indicating the signal sources and signal flow.

7.2 EXPLANATION OF SIGNAL NAME SET UP

7.2.1 Signal names

Signal names consists of 2 parts:

- a functional part of maximal 6 characters
- a realisation part of 2 characters



The realisation part is optional. If it is used then the functional parts should consist of 6 characters. If necessary dummy's (minus signs) are used in the functional part, to make it 6 characters long.

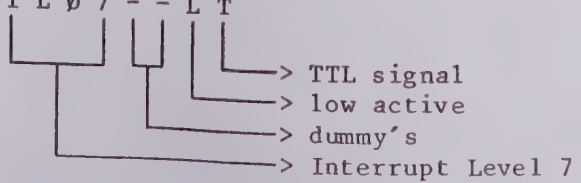
The first character of the realisation part has the following meaning:

H: active high signal
L: active low signal
X: irrelevant (e.g. counter outputs)

The second character of the realisation part is used to identify signal levels:

A: analogue
E: ECL -4,5V or -5,2V
T: TTL 5V or HCT
X: other levels

Example: I L Ø 7 - - L T



Sometimes the functional part can also be used for a serial number e.g. to indicate a buffered version of a signal.

Example: CHPT--Ø1

7.2.2 Signal name list

Each unit description in chapter 8.0 "CIRCUIT DESCRIPTIONS" contains a list with the signal names used in that unit given in alphabetical order.
Behind each name, a description is given and is mentioned on which unit the signal is generated.
Only if the signal is generated on the unit itself, the other units on which the signal is used (signal destination(s)) are mentioned, otherwise a minus sign is filled in.
If the signal flows over more units in sequence, the path is indicated.

Example: The battery voltage (BAVO) comes from unit A66 via A20, A19 and A12 to A6. On unit A66 is indicated: A20-A19-A12-A6.

Some signals may have more signal sources, because the sources have open collector output circuits, or 3-state output circuits.
In this case the sources are mentioned, separated with a plus (+) sign.
As signal source is always indicated, the unit where the signal is generated.

Example: On units A20, A19, A12 and A6, unit A66 is indicated as source.

A number of power supply lines and ground lines, which are generated on POWER 1 unit A19, are not mentioned on the signal name lists because they appear in almost every unit.
These signal names can be found on the signal name list of POWER 1 unit A19 itself, and are in the destination column indicated with "general".
Power supply lines, which are derived from the power supply lines mentioned above, are also not mentioned in the list.

The destinations of the data-bus and address-bus lines from the microprocessor system on MICROPROCESSOR unit A6 are also indicated with "general", because almost all units are involved. This is also done for the signals UPRD--LT (microprocessor read) and UPWR--LT (microprocessor write).

8.1.1 General information

This unit basically comprises the vertical and horizontal final amplifiers, the overscan detection circuit, the Z-amplifier, the calibrator circuit and the analog plot interface.

8.1.2 Vertical final amplifier

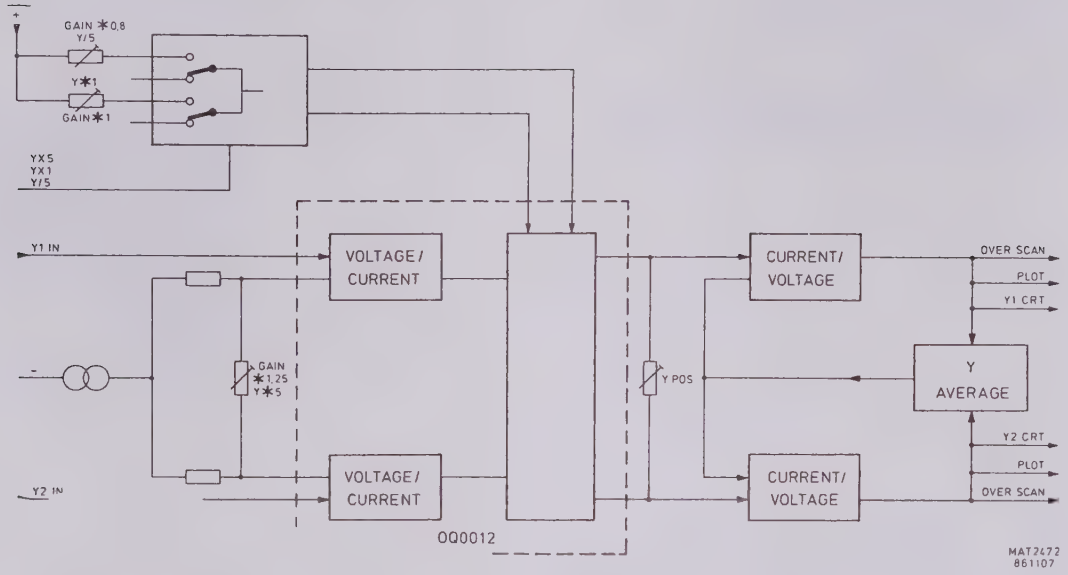

Figure 8.1.1 Blockdiagram Y-final amplifier.

The output signals Y1IN and Y2IN from the DISPLAY DAC UNIT A2 are applied to a voltage/current converter of which the x1,25 (Y*5-mode) gain can be adjusted by potentiometer R2531 in the emitter circuit of the input transistor of D2507.
Furthermore, the gain can be influenced for the Y*1 and the Y/5 mode.
Two sections of multiplexer D2501 can be switched by the signals ANEPY-HT (analog expand) and ANCPY-HT (analog compress) from DISPLAY CONTROL UNIT A3.
The switching is done according the following table:

MODE	ANCPY-HT	ANEPY-HT	analog expand factor (UNIT A1)	digital expand factor (UNIT A2)
Y/5	1	Ø	x0,8	/4
Y*1	Ø	Ø	x1	x1
Y*5	Ø	1	x1,25	x4

An additional circuit can be switched in for the x1 gain (adjustable with potentiometer R2513) and and additional circuit can be switched in for the x0,8 gain (adjustable with potentiometer R2516).
The selection depends on the user selection of the Y*5, Y*1 or the Y/5 mode.

Output points 12/13 and 14/15 of the MULTIPLIER D2506 are applied to current/voltage converters in the Y-OUTPUT stage of which the balance can be adjusted by potentiometer R2533.

The average value of the signals Y1 and Y2 is fed back to the input of the X-OUTPUT stage to keep the average value constant.

The signals X1 and X2 are applied to the vertical deflection plates of the C.R.T., to the OVERSCAN DETECTION circuit on unit A1 and also to the PLOT INTERFACE on this unit A1.

8.1.3 Horizontal final amplifier

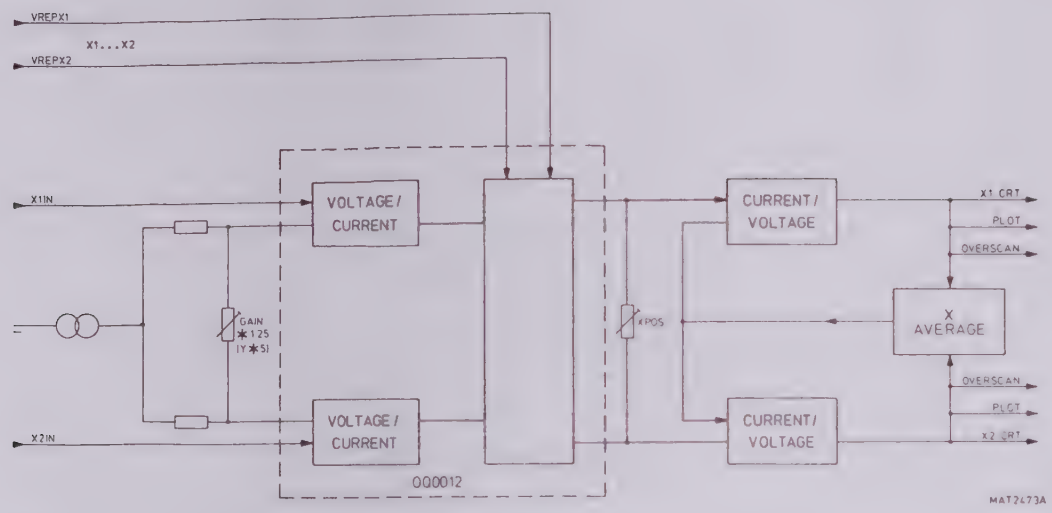

Figure 8.1.2 Blockdiagram X-final amplifier.

The output signals X1IN and X2IN from the DISPLAY DAC UNIT A2 are applied to a voltage/current converter of which the x1 gain can be adjusted by potentiometer R2566 in the emitter circuit of the input transistors of D2507.

Furthermore, the gain can be influenced by signals VREPX1 and VREPX2 which carry a variable X-EXPAND factor between x1/2 (EXPAND x1) and x1 (EXPAND x2). This factor, which is user selected, is multiplied in the stage D2507 to vary the X-gain.

Output points 12/13 and 14/15 of the MULTIPLIER D2507 are applied to current/voltage converters in the X-OUTPUT stage of which the balance can be adjusted by potentiometer R2571.

The average value of the signals X1 and X2 is fed back to the input of the X-OUTPUT stage to keep the average value constant.

The signals X1 and X2 are applied to the horizontal deflection plates of the C.R.T., to the OVERSCAN DETECTION circuit on unit A1 and also to the PLOT INTERFACE on this unit A1.

8.1.4 Trace/Text intensity

The levels ITTR from the TRACE INTENS frontpanel control and ITTX from the TEXT INTENS frontpanel control on C.R.T. CONTROL UNIT A16, are applied to one section of multiplexer D2501. This section, which is switched by the signal DPTR--HT (display trace), switches the trace intensity level to the Z-amplifier when traces have to be displayed and the text intensity level when texts have to be displayed.

8.1.5 Overscan detection

The output signals Y1, Y2, X1 and X2 from the vertical and horizontal final amplifiers are applied to an overscan detection circuit where they are compared with four overscan levels for the top, bottom, left and right sides of the trace area on the C.R.T. screen.

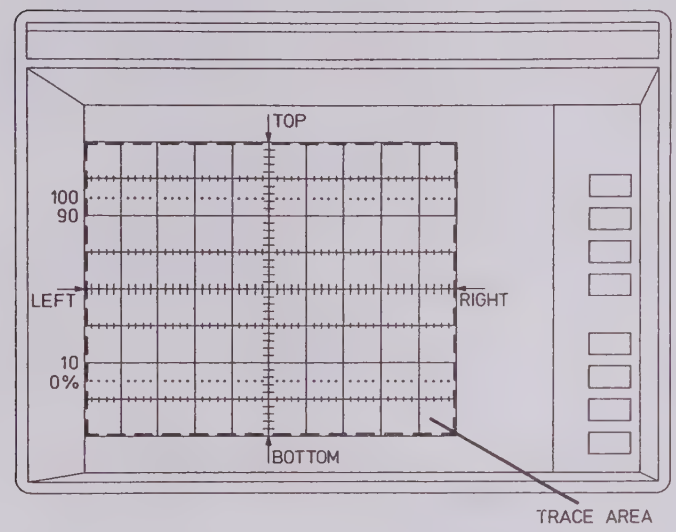

Figure 8.1.3 Overscan detection.

These levels can be adjusted by potentiometers R2658, R2659, R2678 and R2682 in such a way that during the display of traces, the traces can never be displayed outside the trace area on the C.R.T. screen.
In case of overscan a blanking signal is produced by the collector of transistor V2623 and this signal is applied to the Z-amplifier to blank the trace.
The overscan detection circuit can be disabled during text display and enabled during trace display by the signal DIOS--HT (disable overscan) via transistor V2611.

8.1.6 Z-amplifier

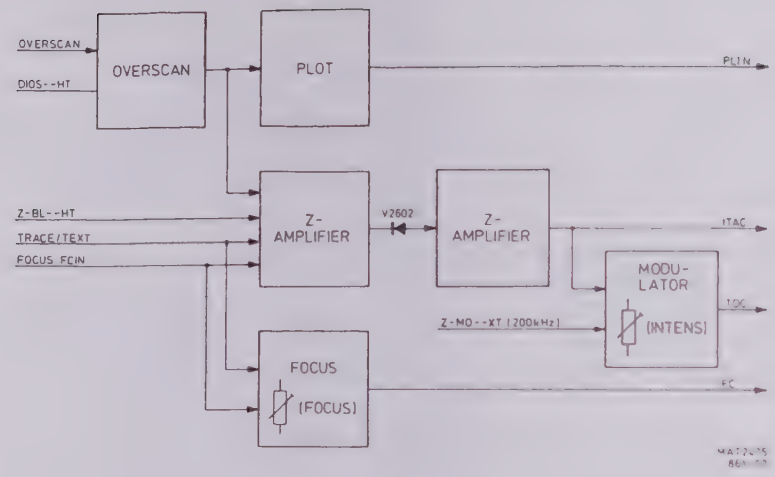

Figure 8.1.4 Blockdiagram Z-circuit.

INTENS

The Z-circuit is controlled by a number of different inputs:

- Overscan
- Z-blank signal
- TRACE or TEXT intensity control level
- FOCUS control level

The signals are applied to a Z-amplifier and the output of this amplifier is guided along two different signal path's. A high frequency component signal path (signal ITAC) and a low frequency component signal path (signal ITDC).
Signal ITAC is directly applied to Z-AMPLIFIER UNIT A15 and from there via a high voltage capacitor to the high voltage part of the circuit and to the intensity grid G1 of the C.R.T..

The low frequency component is applied to a modulation circuit, it can be influenced by a fine adjusting potentiometer R2637 and afterwards modulated with a frequency of 200 kHz from signal Z-MO--XT from the clock generator on the uP unit A6.
The resulting signal ITDC is applied to Z-AMPLIFIER unit A15 and via Z-circuit transferred via a high voltage capacitor to the high voltage part of the circuit. It is then demodulated, combined with the high frequency component and applied to the intensity grid G1 of the C.R.T..

FOCUS

The FOCUS circuit is influenced by the setting of the front panel FOCUS controls as well as the setting of the TRACE and TEXT intensity controls. The last is needed for the auto focus control when the intensity is changed with one of the frontpanel TRACE or TEXT intensity controls. There is also a fine adjustment potentiometer R2609.
The resulting signal FC is applied to the focus circuit on Z-AMPLIFIER UNIT A15 and from there to the focus grid G3 of the C.R.T..

8.1.7 Calibrator

The calibrator circuit is fed by signal Z-MO--XT of 200 kHz which is derived from the CLOCK GENERATOR circuit on the uP UNIT A6. This signal is divided by a factor of 100 by the dividers D2502 into a 2 kHz frequency. It is then applied to a CAL output socket via a stage where the amplitude can be adjusted via R2703. The output signal is a 2 kHz -1Vpp signal (50 Ohm).

8.1.8 Plot interface

The output signals Y1, Y2, X1 and X2 from the vertical and horizontal final amplifiers are applied to a plot interface where they are prepared to be plotted via the rear panel analog plot output socket.

The X-output gain can be adjusted with potentiometer R2728 and the Y-output gain with potentiometer R2738.
Sample and hold signal SAPL activates the interface for a plot action. Signals are only applied to the output socket when enabled by signal PLZEOT if a value is stored in the sample and hold circuit.

A pen lift circuit is activated via the PLIN signal (when an overscan is detected). The penlift flip flop can be reset by the PEN UP signal PU----LT.

The pen lift polarity can be influenced by signal PFPY via exclusive or circuit D2504.

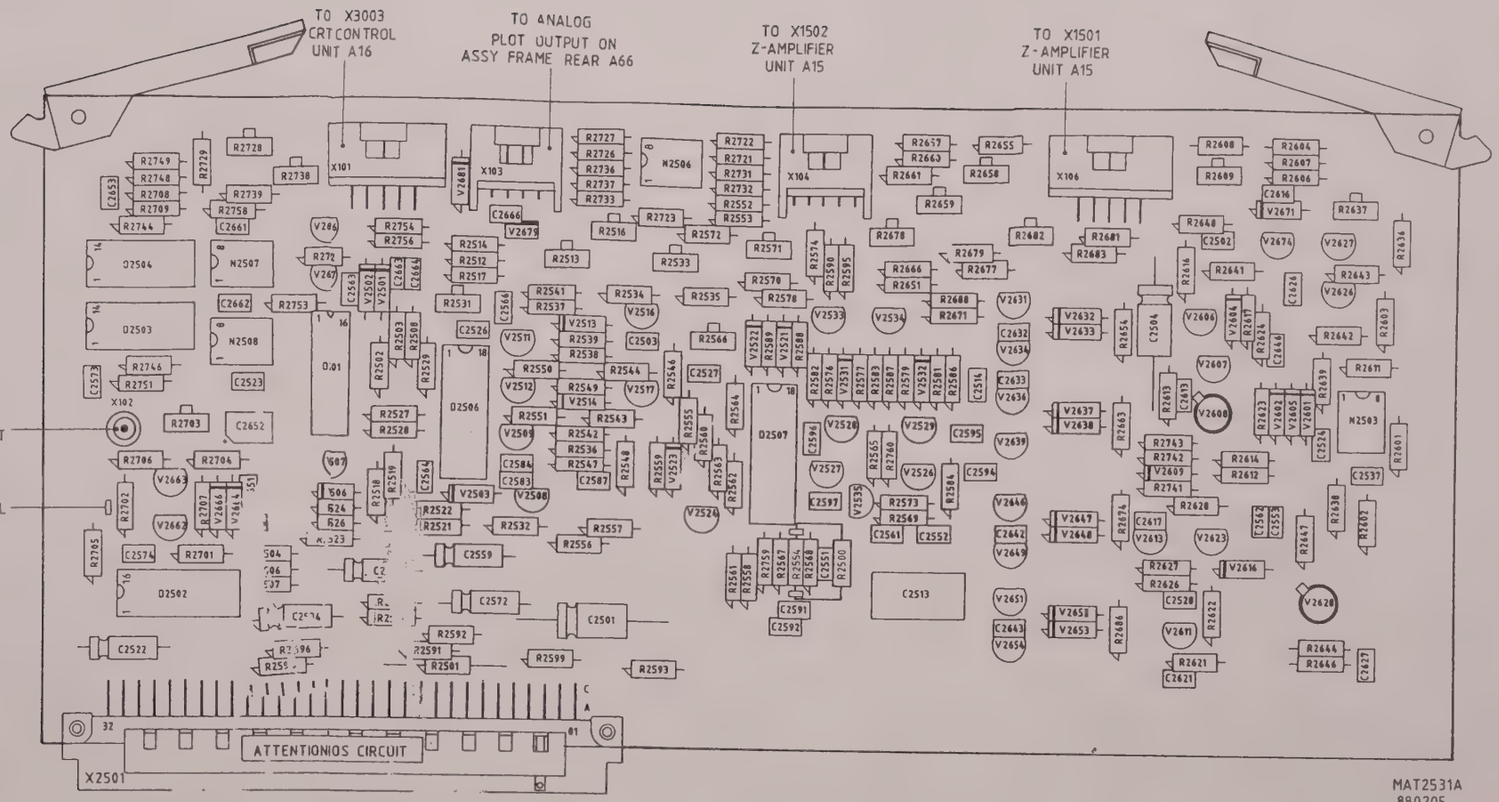

Figure 8.1.5 Unit A1 - FINAL AMPLIFIER UNIT - p.c.b. lay-out.

8.1.9 Signal-name list

UNIT A1

Signal name	Description	Signal source	Signal destination(s)

CONTENTS

8.2.1 General information..... 8.2-1
8.2.2 Vertical data path..... 8.2-1
8.2.3 Horizontal data path..... 8.2-6
8.2.4 X-Variable data path..... 8.2-11
8.2.5 Signal-name list..... 8.2-11

8.2.1 General information

This unit basically comprises the vertical and horizontal position adders and the vertical and horizontal digital to analog converters.

8.2.2 Vertical data path

The vertical trace data as well as all kinds of vertical text data on the ten output lines DCDBØØ...DCDBØ9 of the display control latch is applied to a combined invert/vertical-expand/latch circuit. This circuit consists of the two (not identical) field programmable logic sequencers (FPLS) D2301 and D2302 and the D-type flip flops D2309.
The control signal IVDCDB determines whether the data bits have to be inverted or not and the two control signals EPY-ØØ and EPY-Ø1 determine the vertical expand factor of the circuit.

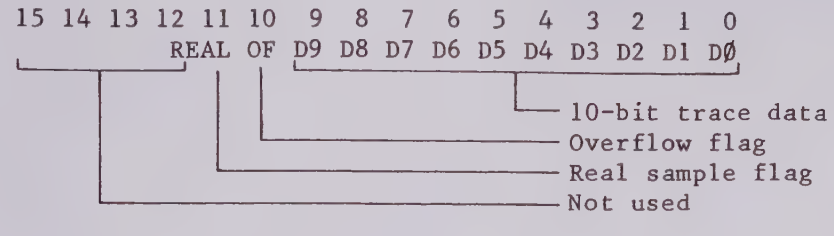
Vertical expand factor	Control signals		Digital expand factor (UNIT A2)	Analog expand factor (UNIT A1)
	EPY-Ø1	EPY-ØØ		
Y/5 (trace)	0	0	/4	/1,25
Y*1 (trace + MSC text)	0	1	x1	x1
line + softkey text	1	0	x4	x1
Y*5 (trace)	1	1	x4	x1,25

The combination of the digital expand factor on the display dac unit A2 and the analog expand factor on the final amplifier unit A1 results in the total required expand factor.
Digital expand is realized by the shifting of the bit pattern two bits to the right (/4) or two bits to the left (x4).
The resulting vertical data is then latched in the output latches of the FPLS circuits and in the four D-type flip flops by signal CKEPVE.

The data can be divided into five different kinds of data.

1) Trace data for X=t display:

Data format:



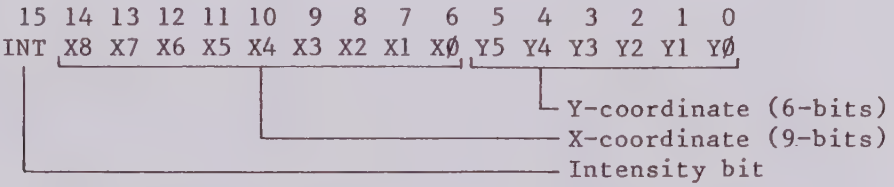
The trace data can be inverted, expanded by factors /5, x1 or x5 before it is applied as EPVEØØ...EPVE11 to the vertical position adder.

2) Trace data for AVSB display:

Data has the same format as for X=t display which is described before. However, only channel B is latched and applied to the vertical position adder.

3) Line text display: Top area text (TAT)
Trace area text (TRAT)
Bottom area text (BAT)

Data format:



Only 10 bits DCDBØØ...DCDBØ9 of this bit pattern are applied to the circuit and only the Y-coordinate bits YØ...Y5 are of interest.
The data is not inverted but expanded by a factor of x4 by shifting the pattern two bits to the left and switching the lowest two bits to zero. Signal ENTXLNLT is active and the output bits EPVEØ8...EPVE11 of D2309 are switched to one.

The final bit pattern is:

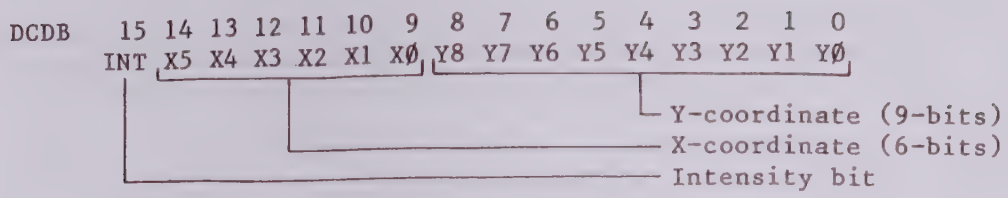
EPVE	11	10	9	8	7	6	5	4	3	2	1	0
	1	1	1	1	Y5	Y4	Y3	Y2	Y1	YØ	Ø	Ø

This pattern is applied to the vertical position adder.

Figure 8.1./ Unit A1 - FINAL AMPLIFIER UNIT - circuit diagram.

4) Softkey text display (SKT):

Data format:



Only 10 bits DCDBØØ...DCDBØ9 of this bit pattern are applied to the circuit and only the nine Y-coordinate bits YØ...Y8 are of interest.
The data is not inverted but expanded by a factor of *4 by shifting the pattern two bits to the left and switching the lowest two bits to zero.

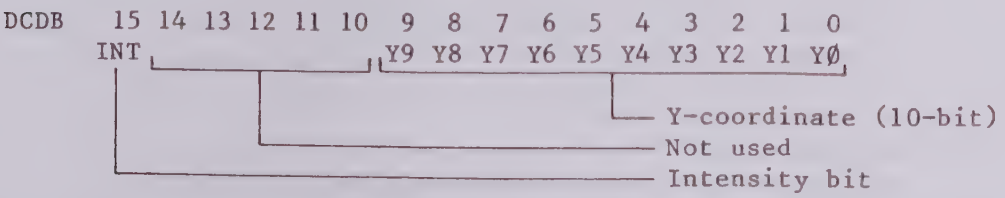
The final bit pattern is:

EPVE 11 10 9 8 7 6 5 4 3 2 1 0
Ø Y8 Y7 Y6 Y5 Y4 Y3 Y2 Y1 YØ Ø Ø

This pattern is applied to the vertical position adder.

5) Miscellaneous text (MCS):

Data format Y-coordinates:



For miscellaneous text, two words, one carrying the Y-coordinate and the other one carrying the X-coordinate, are placed in the text memory for each dot to be displayed.
Only the 10 bits DCDBØØ...DCDBØ9 of the Y-coordinate pattern are applied to the circuit.
The data is not inverted and not expanded.

The final bit pattern is:

EPVE 11 10 9 8 7 6 5 4 3 2 1 0
Ø Ø Y9 Y8 Y7 Y6 Y5 Y4 Y3 Y2 Y1 YØ

This pattern is applied to the vertical position adder.

The output signal Z-OTØ1LT of the first FPLS circuit D2301 is applied to the second one and the output signal Z-OTØ2LT of the second FPLS circuit D2302 is applied to a reflection detection circuit.

The vertical position adder is a sixteen bit circuit which consists of D2319, D2321, D2324 and D2326. A sixteen bit vertical position information is latched in the vertical position latches D2314 and D2316 by signal WRVEPOLT and applied to the other adder input side. This vertical position information is calculated by the microprocessor and depends on the selected vertical expand factor, the use of the Y-POSITION control and the type of trace or text which has to be displayed.

The adder output bits VEDBØ9...VEDB11 are carrying information about reflection and are applied to a Z-detection circuit on unit A3. The following combinations result in light on the C.R.T. screen.

VEDB 11	1Ø	Ø9	Ø8
0	0	0	1
1	1	1	0

All other combinations result in NO light on the C.R.T. screen. This has no function for text display.

The other ten adder output bits VEDBØØ...VEDBØ9 which carry information in two-complement notation, are first converted by the code convert circuit D2338 into straight binary notation by inverting the highest bit VEDBØ9. These converted ten bits are then latched for a time of 750 ns (time between two dots) in a YDAC latch consisting of D2329 and D2331. This is done by the signal LEDA-1HT. It is then applied to the 10-bits vertical digital-to-analog converter YDAC N2301 which has two symmetrical output current lines.
A constant reference voltage +10VREF from differential amplifier N2304 is applied to the YDAC.
The symmetrical output currents of the YDAC are converted into voltage levels by a Hooper stage with low input impedance and low output impedance. This Hooper stage is formed by the transistors V2301 and V2302. The signals are fed then to sample and hold circuits with switches D2341, capacitors C2366 and C2367 and field effect transistors V2303 and V2303 for the deglitching of the YDAC output signals. This is necessary for dot-join display because the trace is constantly unblanked then.
As long as the YDAC outputs are not stable, the switches D2341 are opened by the signal LEDA-1LT and the previous levels are held (for about 125 ns) over the capacitors C2366 and C2367 and at the inputs of the FET transistors V2303 and V2303. After 125 ns the YDAC outputs are stable and the switches are closed. The capacitors can then be charged to the new YDAC output levels. In this way, the YDAC output glitches are suppressed.

For display of only discrete dots, the S/H output signals are applied via an output buffer of two emitter followers V2304 and V2307 with high input impedance and low output impedance as Y1IN and Y2IN to the inputs of the vertical final amplifier stage on unit A1.

For dot-join display an RC-filter with an RC-time of 750 ns (1 dot cycle) can be switched in.
With signal DJAC--HT active, capacitor C2373 will be switched in via switch D2341. In this case only the real samples (512) will be connected with each other with lines between the dots.

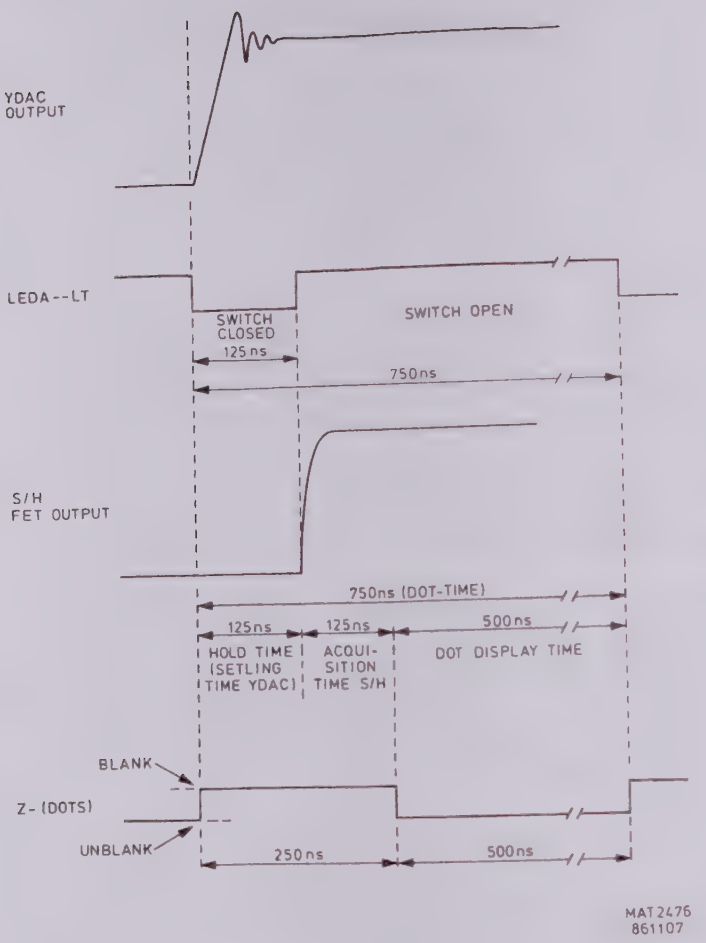


Fig. 8.2.1 Dot cycle

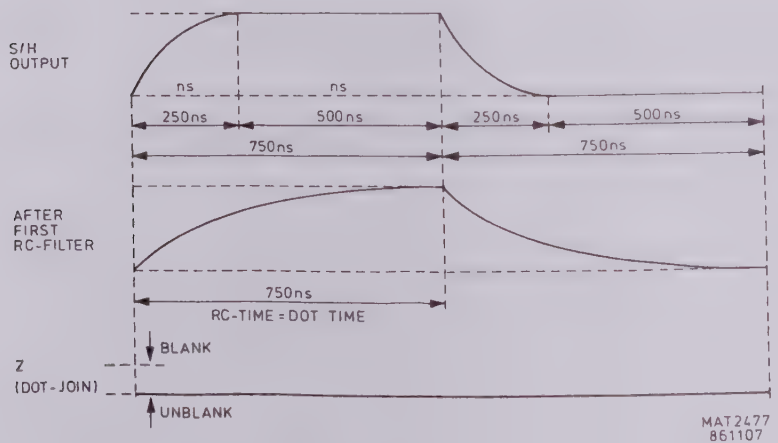

Fig. 8.2.2 Dot join cycle

8

For smooth display not only the dot-join filter is switched in, but also the smooth filter which gives a total RC-time of 7,5 us (10 dot cycles).
This second RC-filter is switched in when signal SM----LT is activated. Capacitor C2369 is switched in via switch D2342 and lines are displayed over ten dots.

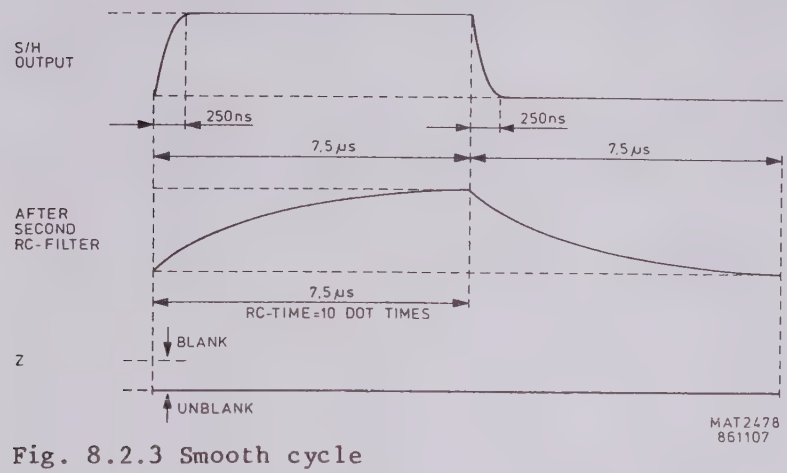

Fig. 8.2.3 Smooth cycle

8.2.3 Horizontal data path

Horizontal data on the expand data bus lines EPDBØØ...EPDB111 can be divided into five kinds of data.

1) Address data for X=t display:

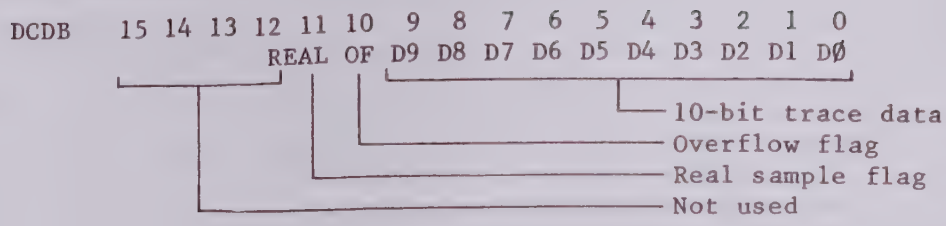
Data format:

DPAB	11	10	9	8	7	6	5	4	3	2	1	0
A	11	10	9	8	7	6	5	4	3	2	1	Ø

12-bit address data from the display address counter on unit A3.

The state of the display address counter is used for horizontal deflection during normal X=t display.
This data is applied to the expand data bus lines EPDBØØ...EPDB11 via the display address data buffer, which consists of D2121 on unit A3 and a part of D2122 on unit A3, when signal HOMO is active.

2) Trace data for AVSB display:



Vertical trace data bits DCDBØØ...DCDBØ9 of channel A for X-deflection in A versus B mode is applied to the expand data bus lines EPDBØØ...EPDB11 via the AVSB trace data buffer, which consists of D2303 and a part of D2304. This buffer is active when signal ENTRHOLT is activated.
The highest bit is inverted by the code convert circuit D2337 to convert the trace data from two-complement notation to straight binary notation. (For channel B this is done in the vertical channel path).
Via the AVSB trace data buffer the data is multiplied by a factor of four to adapt it to the higher horizontal resolution.

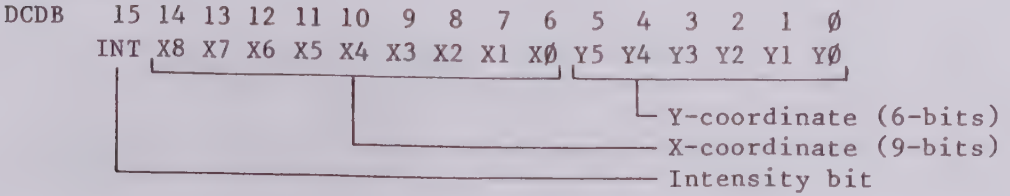
The final bit pattern is:

EPVE	11	10	9	8	7	6	5	4	3	2	1	0
	D9	D8	D7	D6	D5	D4	D3	D2	D1	DØ	Ø	Ø

This pattern is applied to the horizontal expand I circuit.

3) Line text display: Top area text (TAT)
Trace area text (TRAT)
Bottom area text (BAT)

Data format:



Only the 9 X-coordinate bits DCDBØ6...DCDB14 or XØ...X8 are of interest. These bits are applied to the expand data bus lines via the line text data buffer which consists of a part of D2304 on unit A2 and D2124 on unit A3. This buffer is active when signal ENTXLNLT is active. The data is via this line text data buffer expanded to twelve bits of which the lowest three bits are made zero.

The final bit pattern is:

EPDB	11	10	9	8	7	6	5	4	3	2	1	Ø
	X8	X7	X6	X5	X4	X3	X2	X1	XØ	Ø	Ø	Ø

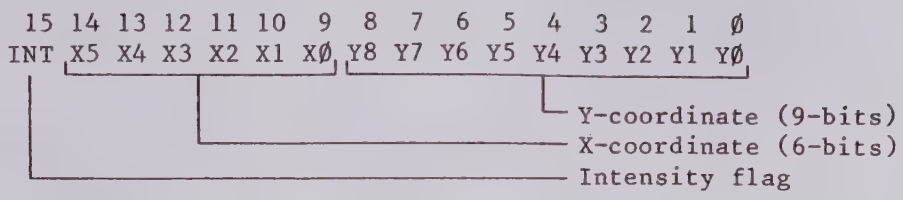
This pattern is applied to the horizontal expand I circuit.

In line text display mode, the X-variable is automatically set by the microprocessor to *1,5.

This results in 512 horizontal text dot positions over 15

4) Softkey text display (SKT):

Data format:



Only the six X-coordinate bits DCDBØ9...DCDB14 or XØ...X5 are of interest. These bits are applied to the expand data bus lines via the softkey text data buffer which consists of D2133 on unit A3 and a part of D2122 on unit A3. This buffer is active when signal ENTXSKLT is active. The data is converted to twelve bits via this buffer. The highest three as well as the lowest three bits are made zero.

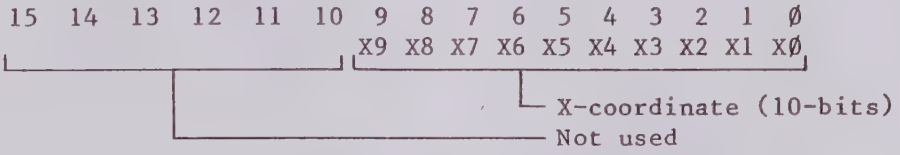
The final bit pattern is:

EPVE	11	10	9	8	7	6	5	4	3	2	1	Ø
	Ø	Ø	Ø	X5	X4	X3	X2	X1	XØ	Ø	Ø	Ø

In softkey text display-mode the X-variable is automatically set to *1,5 by the microprocessor.
This results in 512 horizontal text dot positions over 15 divisions, so with a dot distance of 0,293 mm.

5) Miscellaneous text (MSC):

Data format X-coordinates:



For miscellaneous text, two words, one carrying the Y-coordinate and the other one carrying the X-coordinate, are placed in the text memory for each dot to be displayed.
Only the 10 bits DCDBØØ...DCDBØ9 of the X-coordinate pattern are applied to the circuit. The data is not expanded and the X-variable is set to *1.

The final bit pattern is:

EPVE	11	10	9	8	7	6	5	4	3	2	1	Ø
	X9	X8	X7	X6	X5	X4	X3	X2	X1	XØ	Ø	Ø

The pattern is applied to the horizontal expand I circuit.

The expand databus is connected to the horizontal expand I circuit consisting of a number of multiplexers. The first group D2305, D2307 and D2308 is able to shift the input bit pattern one bit to the left or not. This means that an expand factor *1 is selected if signal EXP-ØØ is "Ø" and that an expand factor of *2 is selected if signal EXP-ØØ is "1". The second group D2311, D2312 and D2313 is able to shift its input bit pattern two bits to the left or not.

This means that an expand factor *1 is selected if signal EXP-Ø1 is "Ø" and that an expand factor of *4 is selected if signal EXP-Ø1 is "1".
The combination of these two groups results in a circuit of which the expand factor can be switched to *1, *2, *4 or *8 depending on the signals EXP-ØØ and EXP-Ø1.

The twelve lines EPHOØØ...EPHO11 of the expand horizontal data bus are applied to one input side of a sixteen bit horizontal adder circuit which consists of D2322, D2323, D2327 and D2328.
A sixteen bit horizontal position information is latched in the horizontal position latches D2317 and D2318 by signal WRHOPOLT and applied to the other adder input side.
This horizontal position information is calculated by the microprocessor and depends on the selected horizontal expand factor, the use of the X-POSITION control and the type of trace or text which has to be displayed.

The signals HODB13, HODB14 and HODB15 are applied to a reflection detection circuit.

The adder output bits HODBØØ...HODB12 are applied to a horizontal expand II circuit which consists of the multiplexers D2333, D2334 and D2336. This circuit can be switched for and expand factor *1, when signal EPX-Ø2 is "Ø" and to a factor *8, when signal EPX-Ø2 is "1".

*1 The address range is shifted three bits to the left resulting in 512 horizontal display positions over ten divisions

*8 Only the lowest 10 bits of the address range is used resulting in an horizontal expand factor of *8.

Data is latched in the multiplexers by signal LEDA--LT and DPRJ.

Ten bits of the horizontal expand II circuit output data are applied to the 10-bits horizontal digital to analog converter XDAC (N2303) which has two symmectrical output current lines. A constant reference voltage +10VREF from differential amplifier N2304 is applied to the XDAC. The symmetrical output currents of the XDAC are furthermore handled like already described under 8.2.2. for the vertical data path. Afterwards they are applied as X1IN and X2IN to the inputs of the horizontal final amplifier stage on unit A1.

8.2.4 X-variable data path

X-variable data which depends on the use of the X-EXPAND rotary controls, is calculated by the microprocessor and placed on the data bus lines DBØ8...DB15. It is then latched in the X-variable latch D2332 when signal WRHOVRLT is active.
It is then applied to an 8-bit X-variable digital to analog converter N2302. A constant reference voltage +10VREF from differential amplifier N2304 is applied to the DAC. The symmetrical output current lines VREPX1 and VREPX2 are applied to the horizontal final amplifier stage on unit A1.

8.2.5 Signal-name list

UNIT A2

Signal-name	Description	Signal source	Signal destination(s)
CKEPVE	Clock expand vertical	A3	-

DPMO--LT	Display mode	A3	A3

8.3.3.14 Start + smooth delay flip flop

The START flip flop is blocked by signal IL05DPLT on input 11 as long as a display preset sequence is performed. At the end of such a sequence a display start signal WRDPSTLT is generated and the start flip flop D2127 produces a 3 us start signal STDP. This STDP signal is applied to the synchronization flip flop D2114 to start the display of a new block.

A new display action can also be started via a RTDP--LT output pulse from the restart-timer.

If SMOOTH is selected, an additional delay of 12 us is introduced by smooth delay flip flop D2127 and a smooth delay signal SMDL--LT is then applied to sychronization flip flop D2116. This is done at the end of a sweep to avoid connection of the last dot of a sweep with the first one of the next sweep.

8.3.3.15 Plot one-shot

If a plot function is selected (signal PLOT active) the plot one-shot D2144 will generate a sample plot pulse SAPL for the analog plot interface on unit A1 at the beginning of the plot block. This is the last block of a display cycle.

In this way one dot per display cycle can be plotted. The minimum plot time is therefore 20 ms/dot. Slower plot speeds can be selected via the PLOT menu.

The microprocessor knows how many dots have to be plotted and which actual dot has to be plotted. The memory addres of the actual dot to be plotted, is presetted in the display address counter and the data which is stored in this addres location is applied to the plot interface on unit A1.

The penlift (pen up/pen down) can be controlled via the microprocessor generated signal PU----LT.

The polarity of the penlift is also generated by the microprocessor by generating signal PFPY.

If the Z-signal is blanked (during overscan for example) the pen is also lifted automatically.

If no plot function is selected, the plot outputs are short circuited via signal PLZEOT.

8.3.3.9 Memory select

The MEMORY SELECT circuit which mainly consists of the FPLA circuit D2151 generates a number of memory select, output enable and write enable signals.

8.3.3.10 Z-detection

The Z-DETECTION circuit which mainly consists of FPLS circuit D2142 generates one output signal Z-BL--HT which carries the blanking/unblanking information for the C.R.T. This signal is derived from a number of input conditions from a number of display circuits.

8.3.3.11 Z-timer

The Z-TIMER is for each block presetted with a value which is calculated by the microprocessor. The value depends on the total number of dots to be displayed during the actual display block. The counter starts counting down latch enable pulses LEDA--HT when enable display count signal ENDPCN is active. Until the end of the counting, when the zero state of the counter is reached, an output signal Z-DP is applied to the Z-DETECTION circuit. The C.R.T. trace can only be unblanked as long as the Z-TIMER is counting and signal Z-DP is generated.

8.3.3.12 Restart timer

This timer especially has a function when X-EXPAND is selected and is for each block presetted with a value which is calculated by the microprocessor. The value depends on the X-EXPAND factor and the total number of dots to be displayed during the actual display block.

If for example the X-EXPAND factor is *4, the display block will be displayed four times in order to reach a same trace intensity on the C.R.T. screen as there is without X-expansion.

After the first display action, when the zero state of the restart timer is reached, and restart display signal RDDP--LT is generated to start the second display action and so on. After display action four (in this example) the end of the complete display block is given by the ILØ5--LT output signal from the interrupt timer.

8.3.3.13 Interrupt timer + flip flop

This timer is for each display block presetted with a value which is calculated by the microprocessor. The value depends on the total number of dots to be displayed during the actual display block. The counter starts counting down latch enable pulses LEDA--HT when enable display count signal ENDPCN is active. At the end of the counting, when the zero state of the counter is reached, an output signal is applied to the interrupt flip flop D2133 and an interrupt signal ILØ5--LT for the microprocessor is generated to indicate the end of the actual display cycle.

8.3.3.6 Address decoder

An address decoder D2132 is able to decode a number of addresses which are generated by the microprocessor.
This results in a number of signals (see also the preset sequence under section 8.3.2) according to the following table.

IOSLØ5LT	UPWR--LT	ABØ4	ABØ3	ABØ2	ABØ1	Output signal
0	0	1	0	0	0	WRDPSTLT
0	0	1	0	0	1	--
0	0	1	0	1	0	--
0	0	1	0	1	1	WRVEPOLT
0	0	1	1	0	0	WRHOPOLT
0	0	1	1	0	1	WRPSDPLT
0	0	1	1	1	0	WRDPPALT
0	0	1	1	1	1	WRHOVRLT

A chip select signal CSZ-CNLT for the Z-counter is generated via D2129 if IOSLØ5LT is active and ABØ4 is logic "0".

The signal overflow status can be read by the microprocessor via data bit DBØØ (D2128-6), which is derived from signal DCDB10 via flip flop D2114. The overflow status (one or more bits in a display block) is read by the microprocessor after each display cycle.

8.3.3.7 Clock fase generator

A binary counter D2134 which can be resetted via the microprocessor reset signal UPRSOTLT counts the pulses from the 8 MHz microprocessor clocksignal DPCKØ8HT.
During each counter cycle, the counter is presetted to the value eleven when its fourth output bit is zero and a new clockpulse appears. The counter then continuous counting which results in the timing clock signals as shown in figure 8.3.6.

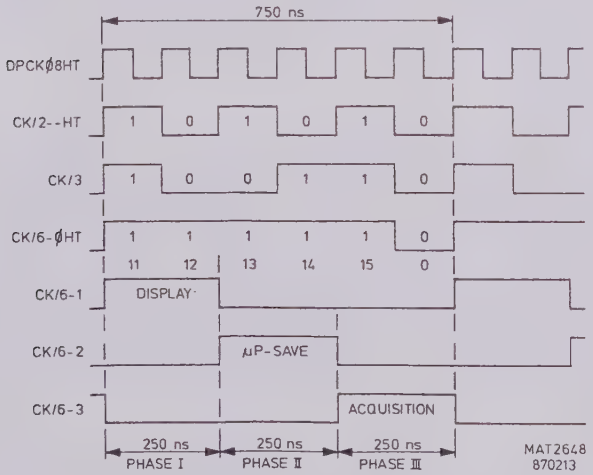

Figure 8.3.6 Clock signals.

8.3.3.8 Copy synchronization one-shot

The COPY SYNCHRONIZATION ONE-SHOT D2144 is used in the ROLL-mode for the synchronization between the display system and the DPU system by generating the synchronize display signal SYDP.
Signal SYDP indicates the end of the display block for register RØ.

8.3.3.4 Display address counter

The DISPLAY ADDRESS COUNTER, consisting of the counters D2111, D2112 and D2113, generates the addresses of the TRACE MEMORY locations to be displayed.

The counter is normally (in single channel mode) presetted to its zero state before a display block starts and the counter counts through ist complete range during a display block.

In dual channel mode however, the counter needs to know whether channel A or channel B has to be displayed. The correct start address of the channel in the TRACE MEMORY has to be presetted by the microprocessor system. The counter counts then with a speed which is twice the speed in single channel mode.

The counter is always presetted by the value which is present in the PRESET REGISTER at the beginning of a display block. Presetting is done under the control of signal DIDPPS. Presetting is stopped at the start of a display block with signal STDP via flip flop D2114. Counting is started then under the control of signal DIDPCN.

The first output bit DPABØØ of the display counter is via multiplexer D2118 applied to the display address bus and influenced depending on the selection of single or dual channel mode.

Single channel mode: (HOMO = "0" and DPMO--LT = "1")

DPABØØ = DPABØØ

Dual channel mode: (HOMO = "0" and DPMO--LT = "0")

DPABØØ = CHID (Channel identification)

CHID = "0" means channel B (odd locations in memory)

CHID = "1" means channel A (even locations in memory)

In dual channel mode, the display counter clockpulse DPCNCK is switched to a speed which is twice the speed used in single channel mode.

The speed is:

1 1/3 MHz in single channel mode (derived from CK/6-ØHT)
2 2/3 MHz in dual channel mode (derived from CK/3)

8.3.3.5 Data buffers

There are buffers D2121 and D2122 (partly) for display addresses, D2122 (partly) and D2123 for softkey text and D2124 for line text.

If R1 or R3 is selected, the output of the SAVE latch is placed on the trace data bus during FASE III, address line TRAB13 is switched to "1" to point to R1 or R3 and the relevant chip select signal is activated.

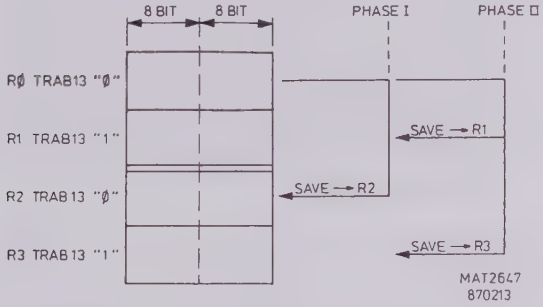

Figure 8.3.5 Save actions.

8.3.3 Circuit descriptions

8.3.2.1 Data buffer

Data from the microprocessor system on the data lines DBØØ...15, which is meant for the DISPLAY CONTROL unit A3, is applied to the internal display data bus lines DPDBØØ...15 of this unit. This data is transferred via the DATA BUFFER, which consists of D2101 and D2102 when the I/O select signal IOSLØ5LT is activated.

8.3.3.2 Preset register

Preset data from the microprocessor system can be latched in the PRESET REGISTER D2103 and D2104 (partly) when the write pulse WRPSDPLT is generated at the beginning of each new display block.
The data on the data lines PSDPØØ... PSDP11 is used to preset the DISPLAY ADDRESS COUNTER with a start value for the next display action. This value depends on the channel which is selected for display, the selected horizontal expand factor or the value which has to be plotted.

8.3.3.3 Output ports display parameters

A number of display parameters can be latched in the OUTPUT PORTS DISPLAY PARAMETERS D2104 (partly), D2106, D2107 and D2108 as described under section 8.3.2.

8.3.2.4 Display timing

The display timing is arranged in such a way that one dot is displayed per 750 ns. Each period of 750 ns is divided into three fases of 250 ns each like shown in the following figure.

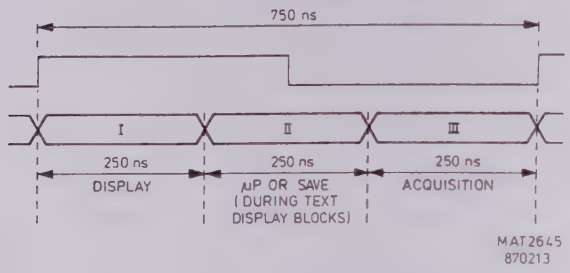

Figure 8.3.3 Display timing.

Fase I is for display actions, fase II for UP or SAVE actions and during fase III acquisition actions can be performed.

8.3.2.5 SAVE timing

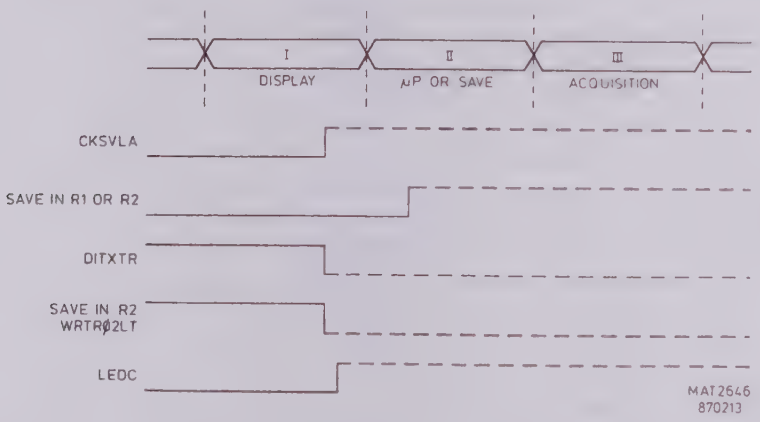

Figure 8.3.4 Save timing.

A save action from RØ to R1, R2 or R3 is done during the display of text blocks. It is done with the first 4096 addresses of the total of 8192 addresses which are generated by the display address counter. Each address is applied to register RØ, to the selected register and to the text memory.

The output data of RØ is latched in the SAVE latch during FASE I with signal CLKVLA.
If R2 is selected for a save action, this register is enabled directly to store the data value.
When this is done, the output of RØ is disabled and the output of the text memory is placed on the trace data bus via the TEXT/TRACE buffer via signal DITXTR. The text can be displayed then.

6 WRHOVRLT Write data to the OUTPUT PORT DISPLAY PARAMETERS D2108 on unit A3 and to the X VARIABLE LATCH D2332 on unit A2.

This is done together with the following signals:

EPY-Ø1	EPY-ØØ	Y-EXPAND
0	0	* 1/4 - Trace
0	1	* 1 - Trace + MSC text
1	0	* 4 - Text (Other)

0 = SKT
1 = Other text

Z-AC Z-active
0 = No light
1 = Light

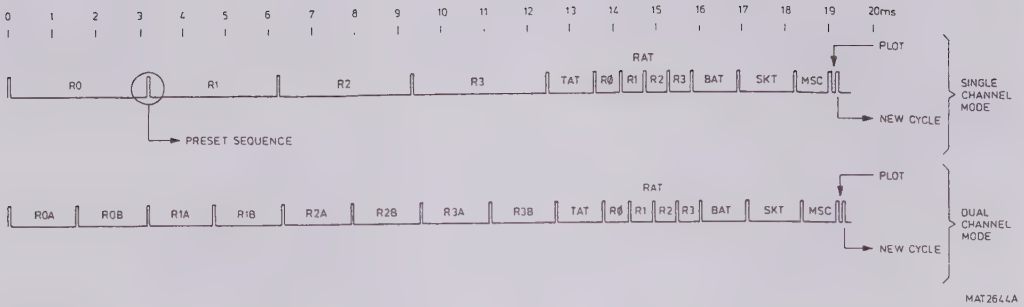

Figure 8.3.2 Display cycle.

8.3.2.3 Preset sequence

After the display of each display block an interrupt level signal ILØ5--LT is send to the microprocessor. The processor in turn starts a preset sequence of new preset values and new parameters for the display circuits. At the end of this preset sequence, signal WRDPSTLT is generated and the display of the next display cycle is started.

Presetting is done in the following sequence:

1 Read overflow bit from DBØØ

2 WRVEPOLT Write the vertical position data to the VERTICAL POSITION LATCH D2314 and D2316 on unit A2.

3 WRHOPOLT Write the horizontal position data to the HORIZONTAL POSITION LATCH D2317 and D2318 on unit A2.

4 WRPSDPLT Write the preset data for the display address counter to the PRESET REGISTER D2103 and D2104 on unit A3.

This is done together with the setting of the signals for the PLOT interface:

PLOT	0 = No sample in S&H
	1 = Sample in S&H
PU----LT	0 = Pen-up
	1 = Pen-down
PFPY	0 = Pen-up (high)
	1 = Pen-up (low)
PLZEOT	0 = Plot output active
	1 = Plot output not active

These four signals are only generated when a plot action has to be performed.

8.3.2 Display system and timing

8.3.2.1 Screen lay out

The screen lay out is as follows.

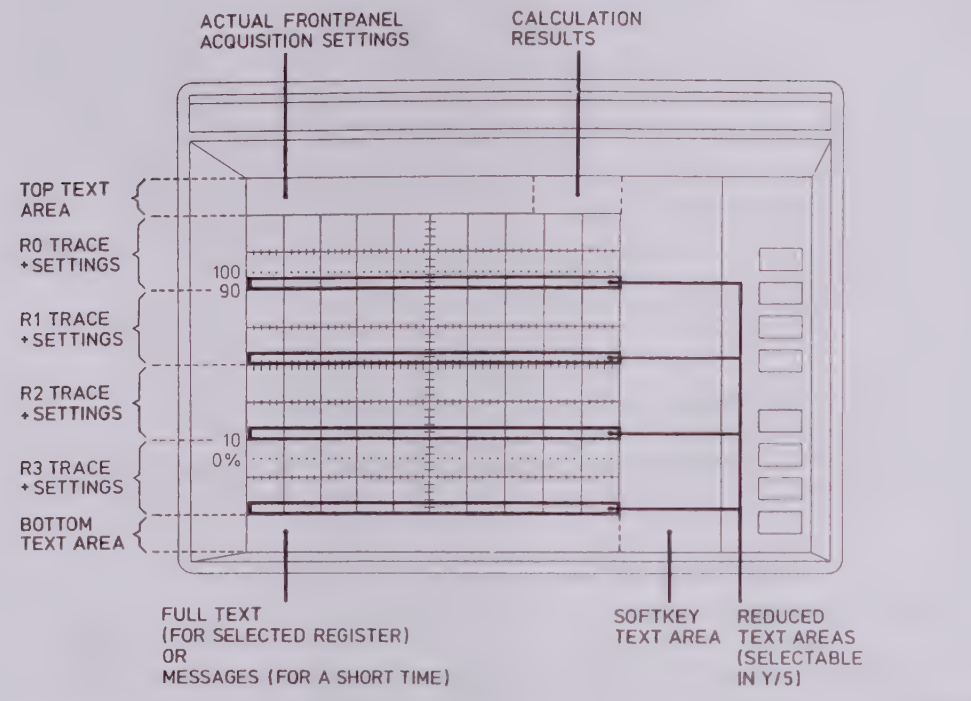

Figure 8.3.1 Screen lay out.

8.3.2.2 Display cycle

During each complete display cycle of about 19 ms the complete contents of the trace memory as well as the text memory is displayed on the C.R.T. screen.

Each display cycle consists of the following display blocks in sequence:

RØ A and/or RØ B	}
R1 A and/or R1 B	} Contents of the
R2 A and/or R2 B	} trace memory
R3 A and/or R3 B	}
TAT	Top text area
RAT RØ	Reduced area text RØ
RAT R1	Reduced area text R1
RAT R2	Reduced area text R2
RAT R3	Reduced area text R3
BAT	Bottom text area
SKT	Softkey area text
MSC	Miscellaneous text (like cursors and channel identification)
PLOT	One dot to plot

8.3.1 General information

This unit contains the circuits needed to control the display circuits on units A2 and A4.

It contains the following circuits:

Data buffer
Preset register
Output ports for display parameters
Display address counter
Data buffers for:
- Display address data
- Softkey text data
- Line text data

Timing circuits:
- Synchronization flip flops
- Data acknowledge flip flop
- Start flip flop
- Smooth delay flip flop

Z + interrupt timer
Z - counter
Interrupt counter + interrupt flip flop
Restart counter
Address decoder
Z - detection circuit
Clock-fase generator
Memory select circuit

8.4.8 Trigger address comparator

The TRIGGER ADDRESS COMPARATOR is part of the address generator on the DPU CONTROL (Unit A8).
D2022 and D2023 form a 12 bit latch, in which data from the DPU address bus (DUABØØ...11) can be loaded by the DAVA signal. It is reset when the DPU (Unit A9) is reset by RSDU--LT.
The address data from the latch is compared with address data on the DPU address bus by a 12 bit comparator (D2024, D2026 and D2027). When both addresses are the same, the signal OTCM is high. This signal is led to the status multiplexer on unit A8.

8.4.5 Reading trace data for display purposes

The display memory addresses which are needed during the display cycle for trace data are generated by a display address counter which is located on the display control unit A3.

The display counter output address bits DPABØØ ... DPAB11 are applied via address multiplexer I and address multiplexer II to the address inputs of the four display registers RØ, R1, R2 and R3.

Each register can be selected for display by the generation of its chip select signal, its output enable signal and the register select signal TRAB13.
The selected register places its output data word on the trace data bus lines TRDBØØ ... TRDB15. This data is applied to the display control latch by latch enable display control latch signal LEDC.
The output data bits DCDBØØ ... DCDB15 are applied then to the display DAC unit A2 for further handling.

8.4.6 Reading text data for display purposes

The text memory addresses which are needed during the display cycle for text data are generated by the display address counter. These display address counter address bits DPABØØ ... DPAB11 are applied via address multiplexer I to the address inputs of the text memory.
The text memory is selected by the generation of its chip select signal, its output enable signal and the register select signal TXAB13. The text output data word is placed on the text data bus lines TXDBØØ ... TXDB15 and via the text/trace buffer consisting of D2006 and D2007 applied to the display control latch.
The output data bits DCDBØØ ... DCDB15 are applied then to the display DAC unit A2 for further handling.

8.4.7 Data communication via options

Instruments which are equipped with option can communicate with the trace memory as well as the text memory via the following signal paths.

Trace memory:

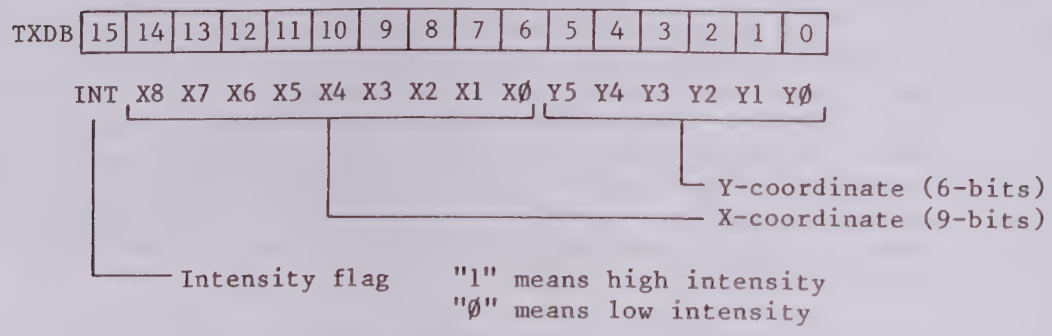
Addresses are generated by the microprocessor and via address multiplexers I and II applied to the display memory.
Data communication is done via the microprocessor data bus, the bidirectional text/trace buffer and the trace data bus or vice versa.

Text memory:

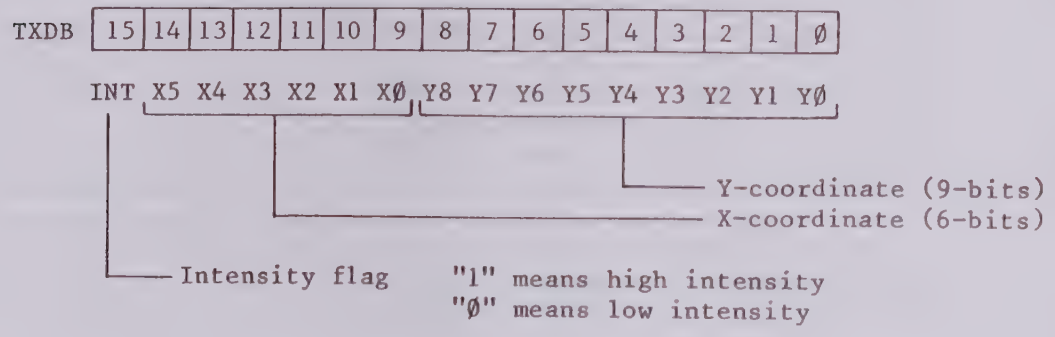
Addresses are generated by the microprocessor and via address multiplexer I applied to the text memory.
Data communication is done via the microprocessor bus, the bidirectional data/text latch and the text data bus or vice versa.

The following text data formats exist:

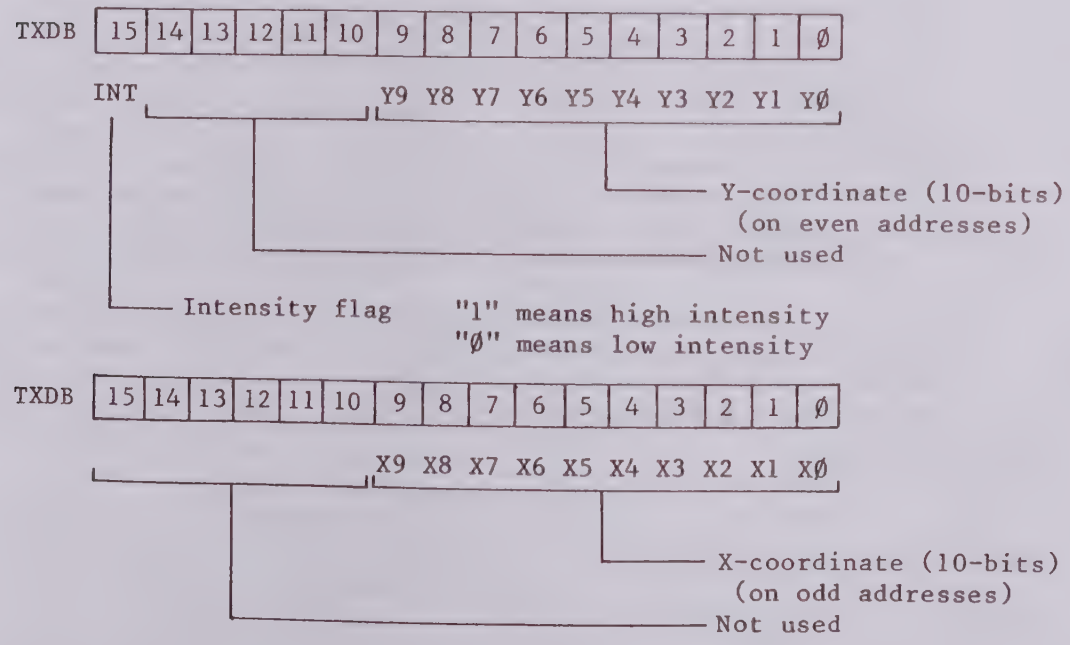
Top area text (TAT)
Trace area text (TRAT)
Bottom area text (BAT)



Softkey text (SKT)



Miscellaneous text (MSC)



For storage of miscellaneous texts, two words are stored, one for the Y-coordinate and the intensity flag and the other one for the X-coordinate.
If no text has to be displayed, a word of only one's will be stored in the text memory and the trace will be suppressed.

8.4.3 Saving trace data from register RØ into one of the registers R1, R2 or R3.

The address information needed for register RØ and the selected register is generated by the display address counter. The address lines DPABØØ ... DPAB11 are applied to the registers RØ, R1, R2 and R3 via address multiplexer I consisting of D2031, D2033, D2032 and D2041 when cycle counter display address bus signal CLDPAB is active and via address multiplexer II consisting of D2037, D2038 and D2039 as TRABØ ... TRAB12 when multiplexed copy address signal MXCPAD is active.

Each trace data word on the register RØ trace data output lines TRDBØØ...TRDB15 is first saved in a save latch consisting of D2028 and D2029 with the clock save latch signal CKSVLA.
The saved word is then afterwards saved in the selected memory by using exactly the same display address. Address line TRAB13 is switched to point to the selected register which is activated via its chip select signal and write enable signal.
The output of the save latch is disabled by the disable save latch signal DISVLA. For the next word the microprocessor increases the address number and so on. After 4096 of these actions the save action is completed. The save latch is not used when data has to be saved in register R2 or R3. Save is then done directly from RØ to R2 and to R3.

8.4.4 Storage of text in the text memory

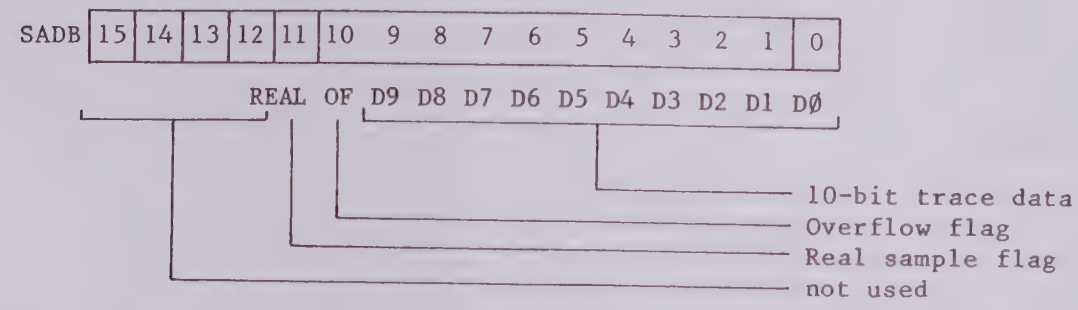
All used kinds of texts are generated by the microprocessor system and stored when they are needed in a 8kx16 bit text memory consisting of D2014 and D2016.
The addresses needed for the storage of text in the text memory are generated by the microprocessor. The microprocessor address lines ABØ1 ... AB12 are applied to the text memory via address multiplexer I consisting of D2031, D2032, D2033 and D2041 as TXABØ1 ... TXAB12.

The text data consists of vertical and horizontal coordinates and an intensity flag. This data is generated by the microprocessor system. The data bits DBØØ ... DB15 are applied via a bidirectional latch consisting of D2003 and D2004 as TXDBØØ ... TXDB15 to the text memory.

8.4.2 Copying trace data from the DPU into display register RØ

On receipt of a trigger pulse, a coupling is realized between the DPU (digital processing unit) and register RØ of the trace memory unit. The DPU places its 12-bit (two - complement) trace data on the sample data bus lines SADBØØ...SADB12. This bus is connected to the trace data latch consisting of D2001 and 2002. Each trace data word is clocked in the latch with signal latch enable display (LEDP). This is done in the rhythm of the acquisition system.

Trace data format:



Signal LEDP switches also a handshake flipflop D2017, resulting in an active SARY (sample ready) signal. When the trace data word is copied to register RØ, the SARYAKLT signal resets the handshake flip flop, which informs the DPU that the next trace data word can be sent to the trace data latch.
In this way the display unit is informed that new trace data is available on the output bus lines TRDBØØ ... TRDB15 of the trace data latch. This trace data bus is connected to the four display registers. New trace data however is always stored in register RØ. This is done in a rhythm which is determined by the acquisition system.
RAM's D2008 and D2009 form together the two 4kx16 registers RØ and R1 and D2011 and D2012 form together the two 4kx16 registers R2 and R3.

Addresses for register RØ needed during the copy cycle of trace data from the DPU into register RØ, are generated by a copy address counter which consists of D2018, D2019 and D2021.
The copy counter address bits CPABØØ ... CPAB11 are applied to the trace register RØ via address multiplexer II consisting of D2037, D2038 and D2039 as TRABØ1 ... TRAB12.
Address line TRAB13 us separately generated and is used for the switching between RØ and R1 or between R2 and R3.

The counter is first resetted to its zero state by signal RSDU--LT (reset DPU). After an active trigger the copy cycle is started and the register will be completely filled once with trace data from the acquisition system. The counter is counting (and thus producing addresses for register RØ. CNCPCN pulses (count pulses for the copy address counter) which are generated in the rhythm in which the acquisition system offers the new trace data. At the end of the copy cycle, the counter generates a signal TCCPCN (terminal count copy adress counter) and the cycle is stopped.

Register RØ is furthermore controlled by its chip select signals CSTR1LLT and CSTR1HLT which can only be active when the memory select down signal MYSLDWLT is not active and by the write enable signal WETRØ1LT.

CONTENTS

8.5.1 General information..... 8.5-1
8.5.2 Memory circuit..... 8.5-1
8.5.3 ACL circuit..... 8.5-2
8.5.4 Signal name list..... 8.5-4

8.5.1 General information

This unit basically consists of the microprocessor memory circuit (RAM) and the acquisition control logic (ACL).

8.5.2 Memory circuit

The microprocessor memory circuit consists of a RAM and some control logic.

The RAM consists of RAM Ø (D1834 and D1836), which is backed up by the battery, and RAM 1 (D1837 and D1838). All devices are 32 kbyte types. If 8 kbyte types are used for D1834 and D1836, then soldering joint J1801 should be changed over.

The ADDRESS REGISTER latches the data of the microprocessor address lines. It is clocked by CKAB--HT, which is active when addresses on the address bus are stable.

The BIDIRECTIONAL DATA buffer buffers the data lines to the microprocessor. It is enabled by CKAB--LT. The direction of data transfer is determined by RARD--LT.

The SELECT LOGIC generates the RAM select signals.
When the power goes down, MYSLDWLT goes low. Now D1833 separates SLØØLOLT and SLØØHILT from the select logic and so they go to VBBa level. The RAMs (only RAM Ø) are deselected, their contents remain.

The remaining select logic generates delayed CKAB signals and DATRAKLT, when this unit is selected.
The delay of the CKAB signals (R1802 and C1851) ensures stable data on the address bus and the data bus when they are clocked in.
The delay of DATRAKLT (R1839 and C1852) ensures enough data setup time for the RAM.

8.5.3 ACL circuit

The ACL circuit consists of the following parts:

- Mode register
- Slow clock generator
- Slow time base logic
- Acquisition control logic
- Shift logic

The MODE REGISTER latches and decodes data from the microprocessor, which are used to control the slow time base logic, the acquisition control logic and the shift logic.

The SLOW CLOCK GENERATOR generates signals, which are used in slow time base modes. These signals are derived from UPCK16, the 16 MHz microprocessor clock. The generated signals are:

Name	Frequency
CKCDOC	16 MHz
TBCKØ8	8 MHz
CKSWTB	1,6 MHz
CK16ØØ	1,6 MHz

The SLOW TIME BASE LOGIC consists of D1801, D1821, D1803 and D1811. It generates various control signals which are used in the slow time base modes.
These are the modes in the time base range500 us/div...360 s/div and the read out cycles of the P^2CCD mode and the random sampling mode.
D1801 is a triple programmable counter; the time base counter.
Counter 1 and counter 2 are cascaded to achieve a dividing range which is big enough to divide the CKSWTB signal down to the desired frequency at the time base setting 360 s/div. The divide ratio is determined by RADBØØ...RADBØ7, which come from the microprocessor.
The output of counter 2 is led to pin 2 of D1811, where it is latched with various other control signals, which may arrive at slightly different times, due to propagation delay times.
At the output of D1811 all signals are available at the same moment.
Counter 3 in D1801 counts down the filling of the P^2CCD with samples, when a new time base setting is selected. When the P^2CCD is filled, a clock is given to pin 11 of D1821, which activates ENSWTB.
The counter is a mono stable count down counter, which is triggered by the RSTB--LT signal.
IC D1803 is an FPLS (Field Programmable Logic Sequencer) that generates 4 acquisition control signals, depending on the selected time base mode.
The ENSWTB signals enables the output signals.
SYSWTBØ1 is a 1,25 us long clock pulse at the falling edge of SWTB.
TKSAØ2 is a 2,5 us long clock pulse at the falling edge of SWTB.
RSMNØ1 and RSMXØ1 are used for the generation of reset pulses on unit A49 for the peak detectors on unit A33. They are only present when MIN / MAX is on.
When an external clock is selected (SLETCK) the external clock (ETCK) is synchronised with SCEVØ1 by D1803.

The ACQUISITION CONTROL LOGIC consists of an FPLS (D1804), a latch (D1822) and a triple programmable counter; the ACL counter (D1802). The counter and the FPLS together generate a number of control signals, depending on the selected time base mode. They are buffered by D1822.

The SHIFT LOGIC generates a TKSA signal for the DPU when a sample, that has to be used, leaves the P^2CCD (see figure 8.5.1).

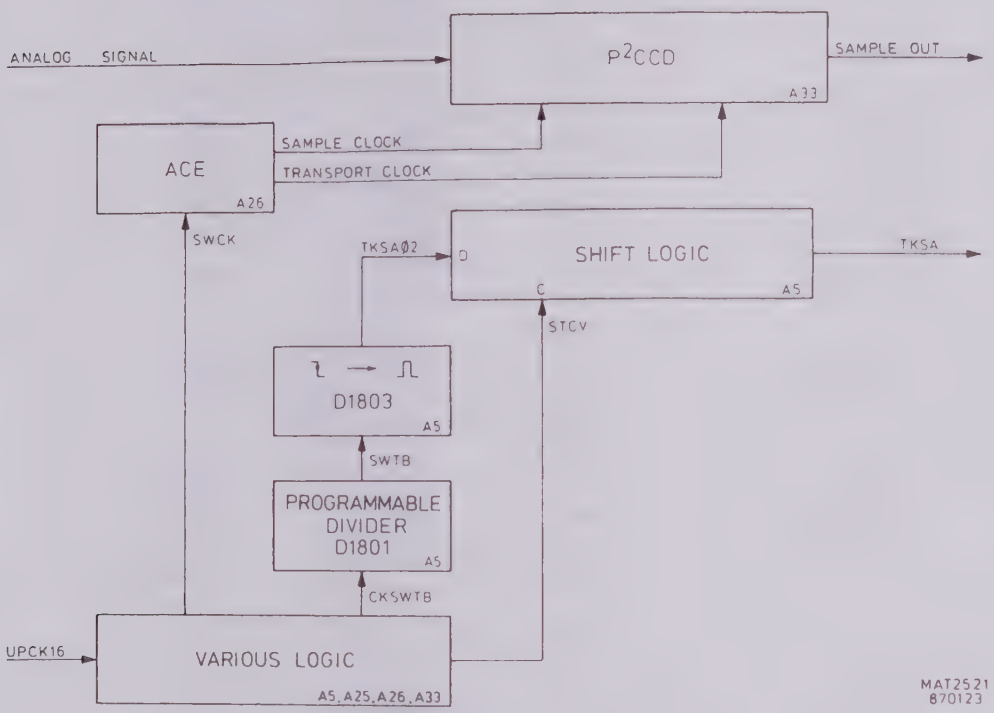

Figure 8.5.1 SHIFT LOGIC

In Direct mode Single channel, the frequency of the sample clock and the transport clock is 400 kHz. So every 2,5 us a sample is taken and transported.
At a time base setting of 100 ms/div every 250 us a sample is used to be displayed (100 ms x 10 div/4K samples). So only 1 of 100 samples is used.
The moments on which a sample is taken, that is to be displayed later, is marked by TKSAØ2, which is derived from SWTB. As the sample is transported through the P^2CCD, TKSAØ2 is synchronously shifted through the SHIFT LOGIC under control of the STCV signal.
When the sample shifts out of P^2CCD the TKSØ2 signal, which is now called TKSA, shifts out the shift logic.

The shift logic consists of IC's D1812...1814 and D1816...1819. D1813 is a quadruple 64-stage shift register, which is connected in cascade to obtain a 256-stage shift register. The number of stages is extended by D1814.
The shift register is clocked by STCV--LT. TKSAØ2 at pin 9 determines wether a "1" or a "Ø" shifts in the register.
D1816 is used to delay some signals and to synchronize them on STCV--LT.
D1817 and D1818 form together a multiplexer, which selects the correct signal in the various modes (TKSAØ1).
D1819 latches TKSAØ1 together with some other signals to offer them

8.5.4 Signal name list

UNIT A5

Signal name	Description	Signal source	Signal destination(s)
ABØ1...16	Address bus Ø1...16	A6+option	-

(1) Becomes BSGRINHT on option.

The INPUT PORT enables the microprocessor to read the status of 3 service switches and the status of the battery.
Service switch X1703 should always be open in this instrument.
Service switches X1704 and X1706 have functions for the diagnostic software (see section 11.4.4).

Via the OUTPUT PORT, the microprocessor generates the watchdog signal WD----LT with the open collector gate D1714. The battery test circuit is also controlled via the output port.

The SUPPLY VOLTAGE SWITCH switches +5D off, when this voltage is too low.
When the power is on, +5D supplies the memories via V1712 and charges the batteries via R1715.
When +5D goes low as the instrument is switched off, V1711 and V1712 block, which prevents that the batteries supply back to +5D.
Now the memories are supplied by the batteries via V1707 and R1715.
V1708 will also block and MYSLDWLT will go down, which will deselect the memories. Their contents will remain.

The BATTERY TEST circuit loads the battery via V1702 and R1712, when the condition of the battery has to be tested after a (re)start of the microprocessor. Because of feedback from +5D via R1715 this circuit is of no use in this instrument. It is present for compatibility with other instruments in which this board is used together with normal (non rechargeable) batteries. In that case R1715 is not present and diode V1707 prevents the batteries from being charged from +5D.

The COMPARATOR compares the battery voltage with a reference voltage from V1701. When the battery voltage is too low, BAST goes high, which is read by the microprocessor via the input port.
When rechargeable batteries are used, the battery voltage should not be too low, due to the feedback via R1715, unless one of the batteries is broken.

The CLOCK GENERATOR consists of a compact integrated crystal oscillator of 16 MHz (G1701) and a number of divider stages. The table below gives the frequency of the generated signals.

Name	Frequency
UPCK16	16 MHz
UPCKØ8	8 MHz
UPCK	8 MHz
Z-MO-XT	200 kHz
TIC	25 Hz

By changing over soldering joint J1707 all frequencies are divided by 2. This can be used to detect access time problems.

The INTERRUPT PRIORITY LEVEL ENCODER (D1708) encodes 7 offered interrupt levels to a 3 bit binary code (IPLØ...2), which is applied to the microprocessor. A reaction of the microprocessor on ILØ1--LT might be postponed a while, because interrupts with a higher priority are present. Now flipflop D1704 keeps ILØ1--LT low, when TIC goes high after 20 ms. When the interrupt is acknowledged the flipflop is reset by TCRS--LT.
Gate D1739 is a buffer between the HCT logic on unit A3 and the LS TTL logic of D1708.
ILØ7--LT (power down) is also routed to the reset/halt logic, to halt the microprocessor.

The WATCHDOG consists of a retriggerable monostable multivibrator (D1709), an oscillator (D1712) and the reset/halt logic.
When the microprocessor program runs normally, the multivibrator is retriggered within every 2 seconds by WD----LT. This keeps pin 12 of D2709 low. Via D1712 UPRSOTLT and UPHA--LT stay high.
When another microprocessor has taken over control over the system, WD----LT is generated by this microprocessor.
If the WD----LT signal does not come within 2 seconds (e.g. due to an abnormal program sequence) pin 12 of D1709 goes high. Now the microprocessor is halted by UPHA--LT and the hardware is reset by UPRSOTLT.
The gate of D1712 pins 1, 2 and 3 forms an oscillator, so after about 2 seconds UPHA--LT and UPRSOTLT become inactive. The microprocessor will restart, generate the WD----LT signal and so on.
If for some reason the microprocessor should not restart correctly the oscillator of D1712 gives a halt plus reset after 2 seconds and after another 2 seconds the microprocessor can restart again. The strap X1708 allows disabling of the watchdog, which is used for the diagnostic software (see section 11.4).
A start of the microprocessor and a restart caused by the watchdog initiates the power up routine (see section 11.4).
If the power goes down ILØ7--LT halts the microprocessor via pin 5 of D1712. Capacitor C1753 keeps ILØ7--LT long enough low at power up, to be sure that all supply voltages are present when the microprocessor starts.
The signal ILØ7--LT is also connected to testpoint X1713, which is located next to ground testpoint X1714.
By interconnecting these testpoints the microprocessor can be restarted.

8.6.4 Circuit description

The MICROPROCESSOR (D1717) is connected via the microprocessor data bus to the BIDIRECTIONAL DATA BUS BUFFER and to ROMØ and ROM1.
ROMØ and ROM1 consists each of two 128K x 8 ROMS, together forming two 128K x 16 ROMs.
If software releases with 64K x 8 ROMS are used, then the soldering joints J1701 and J1702 should be changed over.
The ROMs are addressed via the microprocessor address bus. This bus is buffered to the other units by the ADDRESS BUS BUFFER.
The circuit consisting of D1737, D1741 and D1747 generate the memory select signals and some strobe signals.
The circuit consisting of D1744 and D1746 generate the I/O select signals. Via D1743 and D1714 DATRAKLT goes down with a short delay as one of the I/O select signals goes down.
DATRAKLT can also be pulled down by circuits on other units via pin C8 on connector X1701 and the service switch X1707. This switch can be changed over to generate a data transfer acknowledge by the SLBUENLT signal, which is used by the diagnostic software (see chapter 11.4.4).
The circuit around D1741 generates ROM select signals and some other control signals.
The 3 function control signals are applied to a gate in D1737, which detects the interrupt acknowledge status of the microprocessor, when all function code signals are high. This is used to generate VAPEADLT and memory select control signals.
The monostable multivibrator D1709 keeps the bus busy signal a while active, after the microprocessor has accessed the display RAM. This prevents other microprocessors on options to take over the bus, when the microprocessor has transferred data to the display memory, to assure enough time for the display memory control logic to write the data in the display memory (unit A4).

The BUS ARBITER

The BUS ARBITER consists of a dedicated IC (D1731) and associated logic.
It's main function is to assign control of the microprocessor busses to the microprocessor that claims the control.
When no options are installed in the instrument there is only one microprocessor, so the bus arbiter has no real arbiter function.
If UPAB23 at D1734 pin 13 goes high, then RQCL to the BUS ARBITER goes high. Now the BUS ARBITER circuit makes ABBUENLT and SLBUENLT low, which enables all buffers to the CCU-bus. This enables the microprocessor to access memory and I/O ports on other units via the CCU-bus.
The BUS ARBITER circuit is reset by the microprocessor reset signal (UPRSOTLT) from the RESET/HALT logic.
The capacitors C1754...C1761 and resistor network R1726 give delay times, which time the taking over of the microprocessor busses by another microprocessor.

The associated logic generates a number of control signals for the arbiter function as well as for normal microprocessor functions. The shift register D1748 generates the CLWR--LT signal that lies with its edges between the edges of one of the memory select signals. So first the memory select signal goes down, next the CLWR--LT pulse and UPWR--LT pulse at D1721 come and finally the memory select signal goes high.

A number of I/O select signals select address ranges in the I/O part of the memory map, according to the following table:

Select signal	Selected address range	Used for
IOSLØ3LT	C00000-C1FFFFF	Option
IOSLØ4LT	C20000-C3FFFFF	Front units A13 + A14
IOSLØ5LT	C40000-C5FFFFF	Display unit A3
IOSLØ6LT	C60000-C7FFFFF	CCD logic unit A26
IOSLØ7LT	C80000-C9FFFFF	Management unit A25
IOSLØ8LT	CA0000-CBFFFFF	A.C.L. part unit A5
IOSLØ9LT	CC0000-CDFFFFF	Not used
IOSL1ØLT	CE0000-CFFFFFF	Option

The data acknowledge signal for the microprocessor is generated on this unit (A6) when an I/O select signal is active.When a memory select signal is active the data acknowledge signal is generated on the selected unit via a wired or open collector circuit (DATRAKLT).

8.6.3 Interrupts

Peripheral circuits can generate an interrupt to the microprocessor to ask for special actions. Each interrupt has a priority level according to the table below. The higher the interrupt number is, the higher it's priority level is. Interrupts with a priority level which is lower than or equal to the priority level of the currently being handled interrupt are inhibited, until the higher priority level interrupt is handled.

Interrupt signal	Comes from
ILØ1--LT	Microprocessor unit A6
ILØ2--LT	DPU unit A9
ILØ3--LT	Front unit A14
ILØ4--LT	Option
ILØ5--LT	Display unit A3
ILØ6--LT	Management unit A25
ILØ7--LT	Power 2 unit A20

The functions of the interrupts are:

ILØ1--LT Comes every 40 ms. It starts a scan of the front panel keys and updates the status of the pilot lamps.

ILØ2--LT Marks the end of a DPU program or that the DPU has started to transfer data to the display register RØ.

ILØ3--LT Marks that one of the rotaries on the front panel has been turned.

ILØ4--LT Is reserved for use by an option.

ILØ5--LT Marks the end of a display cycle.

ILØ6--LT Marks that delta-t information is available on the management unit.

ILØ7--LT Marks that the power goes down.

8.6.2 Memory map

Only a part of the complete address range is used, according to the following memory map which also gives the memory select signals.

Address (Hex)		
ØØØØØØ Ø3FFFF	ROMØ	Unit A6
Ø4ØØØØ Ø7FFFF	ROM1	
Ø8ØØØØ ØBFFFF	Not used	
ØCØØØØ ØFFFFF	uP I/O	
	Not used	Outside unit A6
CØØØØØ CFFFFF	I/O	I/O Select
DØØØØØ D1FFFF	RAMØ	MYSLØ1LT Unit A5
	Not used	
D2ØØØØ D3FFFF	Display RAM	MYSLØ2LT Unit A4 + unit A3
D4ØØØØ D5FFFF	DPU RAM + I/O	MYSLØ3LT Unit A8
D6ØØØØ D7FFFF	OPTION 2	MYSLØ4LT
D8ØØØØ D9FFFF	RAM1	MYSLØ1LT Unit A5
DAØØØØ FFFFFF	Not used

8.6.1 General information

This unit mainly consists of a powerfull 68000 microprocessor configuration with EPROM, address decoders, I/O buffers and a clock generator. The microprocessor runs at a clock frequency of 8 MHz.
A bus arbiter has been provided to allow a multiprocessor system, which is used when options are installed in the instrument. The microprocessor has an asynchronous bus structure with a 24 bit address bus and a 16 bit data bus.
Asynchronous means that the microprocessor waits for a "data acknowledge" signal from selected I/O circuitry, before continuing. This enables the microprocessor to handle different access times in I/O circuitry.

8.8.3 Signal name list

UNIT A8

Signal name	Description	Signal source	Signal destination(s)
ABØ2...12	Address bus Ø2...12	A6+option	-
CDRSMO	P2CCD/RS mode	A8	not used
CHPT	Channel pointer	A5	-
CKAD	Clock address register	A8	A8
CKCL	Clock cycle counter	A8	A8
CKCR	Clock control register	A8	A8
CKDUR1	Clock DPU register I	A8	A12-A9
CKDUR2LT	Clock DPU register II	A8	A12-A9
CKDUR3	Clock DPU register III	A8	A12-A9
CKDUØ8LT	Clock DPU 8 MHz	A8	A8
CKDU16LT	Clock DPU 16 MHz	A8	A8
CKF	Clock flags	A8	A12-A9
CKIR	Clock instruction register	A8	A8
CKOR	Clock offset jump register	A8	A8
CKPL	Clock pipeline register	A8	A8
CLØ...1	Cycle Ø...1	A8	A8
CNCPCN	Count copy address counter	A8	A12-A4
CO	Complement	A8	A12-A9
CSDURM	Chip select DPU ram	A8	A12-A9
CYAA	Carry address adder	A8	A8
CYOT	Carry out	A9	-
DATRAKLT	Data transfer acknowledge	A8+A3+A5+ A6+option	A12-A6, A12-option
DAVA--03	Data valid	A5	-
DBØØ...15	Data bus ØØ...15	A6+option	-
DUABØØ...11	DPU address bus ØØ...11	A8	A12-A9, A12-A4
DUCRØØ...11	DPU control register ØØ...11	A8	A8
DUIRØØ...31	DPU instruction register ØØ...31	A8	A8
EC	End of conversion	A11	-
ENCP	Enable copy	A8	A8
ENCPSA	Enable copy sample	A4	-
ENOFD	Enable overflow detection	A8	A12-A9
ENPRCN	Enable pretrigger counter	A8	A8
FBRY	Feedback ready	A8	A12-A9
ILØ2--LT	Interrupt level Ø2	A8	A12-A6
IRABØØ...1Ø	Instruction register address bus ØØ...1Ø	A8	A8
IS	Initialisation	A8	A8
LDPRCNLT	Load pretrigger counter	A8	A8
LEDP	Latch enable display	A8	A12-A4
MMPT	Min/max pointer	A5	-
MYSLØ3LT	Memory select Ø3	A6	-

The ADDRESS GENERATOR generates addresses for the pretrigger ram, the average ram and the flag ram on the DPU.
It consists of the following parts:

- buffer
- offset jump register
- address register
- adder
- pretrigger counter
- multiplexer
- trigger address comparator

The BUFFER is a 12 bit buffer (D1421 + D1422), which latches data from the microprocessor. It is clocked by SLOT4.
When OTDIPR is low the data are put on the DPU address bus (DUABØØ...11).DUABØØ is also led to the status multiplexer.

The OFFSET JUMP REGISTER (D1436, D1419 + D1437) consists of two parts. If OTENDT is low, D1436 and D1437 latch DUCRØØ...11, which is the offset jump. D1436 and D1437 are clocked by CKOR, which is derived from bit 14 of the program word. The output signals are applied to the adder.
If OTENDT is high DBØ8...DB15, which represent delta-t information is latched by D1419 on SLOT2. D1437 is reset.
The output signals of D1419 and D1437 are applied to the adder.
Due to the inverter D1406 either the outputs of D1436 or D1419 are enabled.

The ADDRESS REGISTER (D1443 + D1444) is a 12 bit latch, which latches data from the DPU address bus. It is clocked by CKAD. It can be reset by RSAD--LT.

The ADDER is a 12 bit adder, which adds data from the offset jump register and the address register. The carry signal (CYAA) is led to the status multiplexer.

The PRETRIGGER COUNTER (D1453, D1454 + D1456) is a 12 bit presetable up/down counter.
The preset value is loaded from the DPU address bus by LDPRCNLT. The counter value is applied to the pretrigger address bus (PRABØØ...11). When all counter bits are "1" TCPRCN is generated by D1404. It is led to the status multiplexer.
In the direct mode and the roll mode the counter is used as a pretrigger counter. In the other modes it is used for various functions.

The MULTIPLEXER (D1449, D1451 and D1452) selects data from the adder or from the pretrigger counter. The data are applied to the DPU address bus.
When SLPRAB is low, the data from the adder are selected, otherwise data from the pretrigger is selected.
Because OTDIPR and OTDIMX are in antiphase (D1406 pin 3 and 4) either the buffer or the multiplexer writes data to the DPU address bus.

The TRIGGER ADDRESS COMPARATOR is fitted on unit A4. Therefore it is described in chapter 8.4.

The START/STOP LOGIC mainly consists of FPLS D1452 (Field Programmable Logic Sequencer). It generates a number of control signals depending on the status of its input signals.
Three outputs and the output of the status multiplexer are latched by IC D1458. The four outputs determine via the address multiplexer the four most significant address bits of the next instruction. If output pin 16 or pin 17 of D1457 goes low ILØ2—LT is generated via D1404. The microprocessor reads then via D1423 the status of both outputs. The going low of pin 16 marks that the DPU has started to fill display register RØ with samples (ROLL mode and DIRECT mode). The going low of pin 17 marks that the DPU has finished its program.

The STATUS MULTIPLEXER consists of two 1 of 8 multiplexers (D1402 and D1403), which form together a 1 of 16 multiplexer.
The status signal that is selected is determined by the SLSSØØ...Ø3 signals from the pipeline register b.

The ADDRESS MULTIPLEXER (D1409, D1411 and D1412) is a 12 bit multiplexer of which 11 bits are used.
When a DPU program is executed SLAB is low. NXABØØ...NXØ6 and four output signals of D1458 are selected. The address of the next word in the control memory is determined by the 7 less significant bits of the current word and the signals SS1, IS, CLØ and CL1.
When a DPU program is loaded in the control memory by the microprocessor, SLAB is high. The address where the word is loaded is determined by the address selected by the microprocessor.

The CONTROL MEMORY is a 2048 x 32 ram. It is built with four 2048 x 8 ram´s (D1426...1429). SLOTØ is the write signal for the lower 16 bits of a word, SLOT1 is the write signal for the higher 16 bits of a word.
When a DPU program is executed both are high, which results in the read status of the ram. The data on the DUIR bus are determined by the address on the IRAB.

The buffer is a 32 bit buffer (D1413, D1414, D1416 and D1417) between the microprocessor data bus and the DUIR bus. It seperates data on both buses when a DPU program is executed.
When a DPU program is loaded, data from the microprocessor are transferred to the control memory by the SLOTØ and SLOT1 signals, which also control the control memory.

The PIPELINE register is a 32 bit register (D1431...1434), which holds the current instruction, while the next instruction is fetched from the control memory. It is clocked by CKPL, which is generated by the start/stop logic.
At the outputs of the register the definition of the program word can be recognized.

The INSTRUCTION REGISTER (D1441 + D1442) is a 12 bit latch, that latches 12 signals for the DPU. It is clocked by CKIR, which is derived from bit 12 of the program word via D1459.

The CONTROL REGISTER (D1438 + D1439) is a 12 bit latch, that latches 12 signals, which are mainly used on this unit. It is clocked by CKCR, which is derived from bit 13 of the program word.

bits ØØ...Ø6	are the 7 less significant bits of the address of the next instruction
bit Ø7	marks the end of a program
bits Ø8...11	selects statusbit in case of a conditional jump
bit 12	if set bits 16...27 are data for the instruction register
bit 13	if set bits 16...27 are data for the control register
bit 14	if set bits 16...27 are data for the offset jump register
bit 15	if set it generates the signal CSDURM for the DPU
bits 16...27	data for the instruction register or control register or offset jump register, depending on the status of bits 12...14
bits 28...31	if set they generate respectively the signals CKDUR1, CKDUR2LT, CKDUR3 and RDDURM for the DPU.

The control memory may contain one or more programs with a maximum length of 128 words (7 address bits).
The program which is selected depends on the 4 most significant address lines (bits Ø8...11).
The DPU CONTROL consists of the following parts:

- address decoder
- mode register
- start/stop logic
- status multiplexer
- address multiplexer
- control memory
- buffer
- pipeline register
- instruction register
- control register
- address generator

The ADDRESS DECODER, which mainly consists of IC D1401, decodes some address lines from the microprocessor to the select signals SLOTØ...6. Because the logic on this unit is fast enough, the DATRAKLT signal can go low immediately when MYSLØ3LT goes low.
IC D1424 generates a clock signal for the mode register when SLOT2 goes low and the SLAB signal when UPSL goes high.
Furtheron this part contains some buffers for clock signals.

The MODE REGISTER (D1418) is an 8 bit latch that latches data from the microprocessor for the control of the start/stop logic.

Other functions are:

- Roll mode:	roll effect
	digital Min / Max
- Direct mode:	pretrigger
	digital Min / Max
- P^2CCD mode:	digital leakage correction
	linear interpolation
	delta-calculation in maximum resolution mode
- Random sampling mode:	digital leakage correction
	delta-t calculations
- All modes:	flag handling (e.g. overflow)
	averaging

Digital leakage correction is explained in chapter 8.33.3.3.
Digital Min / Max is explained in chapter 8.33.3.5.

To perform these functions there are lines to the Acquisition Control Logic on unit A5, the ADC on unit A11 and the Display Memory + Control on units A3 and A4.
The Data Processor gets its programs for the various modes from the microprocessor.
When a program is finished or other DPU actions have to be reported, an interrupt to the microprocessor (ILØ2--LT) is generated.
A part of the DPU CONTROL is fitted on unit A4. This trigger address comparator (TACM) is marked with a dashed square in figure 8.8.1.
Normally it is rather difficult to check the proper operation of the Data Processor. Therefore it is recommended to use the "DPU test", which is in the diagnostic software (see chapter 11).

8.8.2 Circuit description

The DPU (unit A9) performs the calculations on the sample data. To be able to do this, it receives a number of control signals and addresses from the DPU CONTROL.
These are derived from program words that are stored in the control memory.
The format of these 32 bit program words is defined as follows:

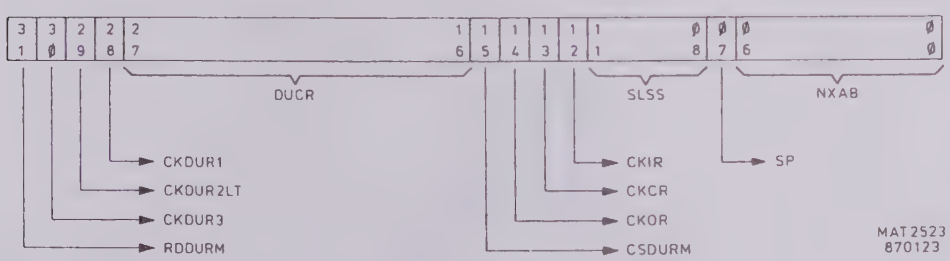

Figure 8.8.2 Program word format.

The DPU control forms together with the DPU (Data Processing Unit) a fast Data Processor with an instruction cycle time of 125 ns.
The main function of the Data Processor is to accept sample data from the ADC, to perform calculations on it and to load the data in register RØ of the Display unit (see figure 8.8.1).

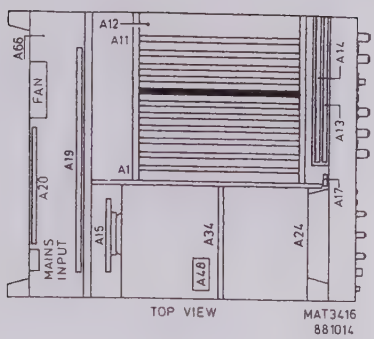
UNIT A7 - OPTION 1



CONTENTS

8.7.1 General information..... 8.7-1

8.7.1 General information

This OPTION 1 slot is reserved for an optional printed circuit board.

An optional printed circuit board in this slot is not available in standard instruments.

A second slot (OPTION 2) is also available in this instrument (see section 8.10.1).

NOTE: The first option to be installed in this instrument must always be placed in the OPTION 1 slot. The OPTION 2 slot may only be used if an option is installed already in the OPTION 1 slot.

CONTENTS

8.9.1 General information..... 8.9-1
8.9.2 Circuit description..... 8.9-1
8.9.3 Example of DPU operation..... 8.9-4
8.9.4 Signal name list..... 8.9-5

8.9.1 General information

The DPU (Data Processing Unit) forms together with the DPU control (unit A8) a fast Data Processor. It is recommended to read first chapter 8.8.1 and 8.8.2 before reading chapter 8.9.2.

8.9.2 Circuit description

The DPU consists of the following parts:

- buffer
- register I
- complementer
- adder
- register III
- overflow detection
- reflection suppression
- shift register
- limit detection
- register II
- pretrigger ram
- average ram
- flag ram
- flag handler

All these parts, excepted the adder and the overflow detection, are interconnected via the 16 bits wide DPU data bus (DUDBØØ...15).

The BUFFER is a bidirectional data buffer (D1203, D1204 and D1206). To convert the 12 sample data bits to 16 DPU data bits SADB11 is applied to DUDB11...15.
Ten processed sample data bits (SADBØØ...Ø9) are applied to the display memory (unit A4).
When OTDIAD is low, data are transferred from the ADC (unit A11) to the DPU. When OTDIAD is high and FBRY or LEDP are high, data is transferred from the DPU to the display memory.

REGISTER I (D1216 + D1217) is a resettable latch, which is clocked by CKDUR1. It is used for various latching functions.

The COMPLEMENTER (+/-) complements data (D1211...D1214). It is used for substractions with the adder.
Because the DPU calculates in two's complement notation, after complemention 1 should be added to get the correct negative number. This is done by the CO signal on the carry input of the adder (D1218 pin 7).

The ADDER (D1218, D1219, D1221, D1222) adds the data from the complementer and register I.
The carry signal at pin 9 of D1222 can generate the CYOT signal via some logic (D1223).

REGISTER III (D1224 + D1226) is a latch, that latches the output result of the adder. It is clocked by CKDUR3.

The OVERFLOW DETECTION (D1231 and associated components) latches on CKDUR3 an overflow bit from D1228 pin 3 and a sign bit from D1222 pin 10 in D1231. So the two bits belong to the data that is clocked in register III. The table below shows which overflow is selected:

SLOFAD	ENOFD	Overflow from
X	0	always "1"
0	1	ADDER
1	1	ADC

Via the logic in D1227 the OTDI3 signal enables wether register 3 by OTEN3-LT or the reflection suppression by OTENRSLT, depending on the presence of overflow.

D1254 decodes the OEDUØØ and OEDUØ1 signals to register control signals, which are active when RDDURM is low.

The REFLECTION SUPPRESSION (D1236...D1239) puts data on the DPU data bus when an overflow occurs, instead of Register III. It consists of a multiplexer, that selects 0000 0000 0011 1111 or 1111 1111 1100 0000, depending on the sign bit from D1231 pin 8.
This circuit prevents the arise of reflection of the input signal in the bottom of the display when high input voltages cause overflow in the display amplitude.
The same is valid in the top of the display with high negative input voltages.

The SHIFT REGISTER (D1242 + D1243) reads data from the DPU data bus, shifts them (left or right) and writes them back to the DPU data bus. This is used for multiplication or division by factors which are a multiple of 2.
The contents of the shift register can be cleared by RSSR--LT, which is used to write zeroes to the DPU data bus.
The signals SFSRØØ and SFSRØ1 determine the function of the register (shift left or right, load or hold) on the clock signal CKSR.

The LIMIT DETECTION detects wether DUDBØ4...11 are all zero or one. This means that the data on the data bus represents a number that is between -16 and +16. This is used for some calculations.

REGISTER II (D1207 + D1208) is a latch, which is used for the intermediate storage of calculation results. It is clocked by CKDUR2LT. When OTDI2 is low, the register writes it's data to the DPU data bus.

The PRETRIGGER + AVERAGE RAM consists of two 8Kx8 rams (D1249 + D1251), forming together an 8Kx16 ram. The lower address range is used as a 4Kx16 pretrigger ram. The higher address range is used as a 4Kx16 average ram.
The addresses for the ram are generated by the address generator on the DPU control (unit A8).
The highest address bit of the ram (pin 2) determines wether the pretrigger or the average ram is selected.
In the pretrigger ram a data word consists of 14 data bits, a real sample flag bit and an overflow flag bit.
In the average ram a data word consists of 16 data bits.

The FLAG RAM consists of a REAL SAMPLE FLAG RAM and an OVERFLOW FLAG RAM. Each consists of a 4Kx1 ram (D1252 and D152), which contain the flags for the data in the average ram.
A real sample flag indicates wether a sample is a real taken sample or a sample that is obtained by means of interpolation between two real samples.
An overflow flag indicates an overflow of a sample. If one or both of two real samples behind each other have an overflow flag, all interpolated samples between them have an overflow flag.

The main functions of the FLAG HANDLER (D1241 and D1232...D1234) are given in the table below.

RDDURM	SLAM	Function of flag handler
0	0	Write flags (STRFL and STOFF) in pretrigger ram.
1	0	Read flags from pretrigger ram and write flags to D1233 and/or to display memory (unit A4) via D1232.
0	1	Write flags in flag ram (D1252 and D1253). Connect DUDB14 and DUDB15 to two MSB's of average ram (D1251 pin 18 + 19)
1	1	Read flags from flag rams to D1233 and to display. Connect two MSB's of average ram to DUDB14 and DUDB15.

The circuit consisting of D1233 and the gates behind, generates an overflow flag for interpolated samples if one of the real samples has an overflow flag.

Note: the overflow flags are not used in this instrument, but they can be read by an option.

8.9.3 Example of DPU operation

The following example describes in a simplified way the calculation of 7 interpolated samples between 2 real samples.

It is supposed that:

- a sweep of real samples is placed in the pretrigger ram.
- the distance between 2 real samples is 8 address locations.
- the intermediate locations have to be filled with interpolated samples.
- none of the real samples has an overflow flag.

The next actions are taken by DPU:

1: copy a real sample from the pretrigger ram to register II and to the shift register.

2: copy the next real sample to register I.

3: enable the register II outputs and activate CO (complement); the inverted first sample is applied to the adder.

4: now the adder subtracts the first sample from the second sample.

5: clock the sample difference in register III.

6: copy the sample difference to register I.

7: in the meanwhile the shift register has shifted left three times, which means that the sample value is multiplied by 8.

8: add the shift register contents and the sample difference.

9: clock the result (interpolated sample x8) in register III.

10: copy the contents of register III in the shift register.

11: by the enabled register III the next interpolated sample x8 is offered to the inputs of this register via the adder and the sample difference in register I.

12: clock this next interpolated sample in register III.

13: the shift register shifts right three times; the result is an interpolated sample.

14: copy the result to the pretrigger ram.

15: repeat steps 10 to 14 another six times for the remaining calculations of interpolated samples.

NOTES: - For obtaining maximum accuracy, the sample difference is not divided by 8, but the sample values are multiplied by 8.
- The complex address generation for the pretrigger ram is done by the address generator on the DPU control.

8.9.4 Signal name list

UNIT A9

Signal name	Description	Signal source	Signal destination(s)

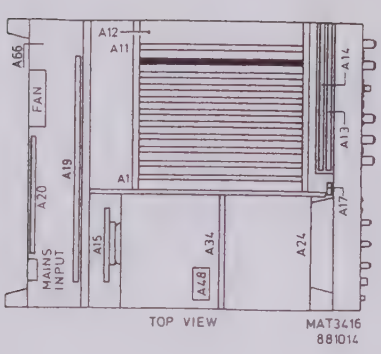
UNIT A10 - OPTION 2



CONTENTS

8.10.1 General information..... 8.10-1

8.10.1 General information

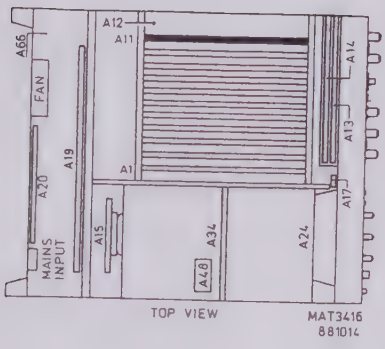
This OPTION 2 slot is reserved for an optional printed circuit board.

An optional printed circuit board in this slot is not available in standard instruments.

A second slot (OPTION 1) is also available in this instrument (see section 8.7.1).

NOTE: The first option to be installed in this instrument must always be placed in the OPTION 1 slot. The OPTION 2 slot may only be used if an option is installed already in the OPTION 1 slot.

UNIT A11 - ADC + T&H UNIT



CONTENTS

8.11.1 General information..... 8.11-1
8.11.2 Circuit description..... 8.11-2
8.11.3 Signal name list 8.11-3

8.11.1 General information

The ADC and T&H unit accepts the samples from one or both input channels from the P^2CCD unit and converts these samples into 12 bits binary codes, which are routed to the DPU (unit A9) for further digital processing.

8.11.2 Circuit description

The samples come from the P^2CCD unit (THINAN) every 2,5 microsecond. They are applied to the CORRECTION CIRCUIT. This circuit compensates some non-linearity of the P^2CCD´s.
IC D616 is a multiplier, whose multiply factor is influenced by the setting of the LINEARITY potentiometer R721, through which correct compensation can be achieved. At the output signals at pin 15 and pin 16 an adjustable offset voltage is added by the circuit around stabiliser N607. The offset can be adjusted with the potentiometer R705.
The signal at pin 15 is applied to a T&H gate (D613 and associated components) via R707.

This T&H tracks the input signal continuously until the signal STCV-1 goes high. Now the output of D613 (pin 12) is held at the momentary value of the input signal.
Its output voltage goes via a buffer amplifier (V607, V608 and V609) to another buffer amplifier; N601 and associated components.
From this buffer amplifier the signal (THOTAN) goes to the ADC.
This buffer amplifier gives a feedback in the track mode (N601 pin 10) to the T&H gate. It is also a separation between the ADC and the T&H gate.

The signal THOTAN is applied to the ADC.
The ADC starts the conversion on the STAD--HT signal from the ADC logic. During this conversion the T&H gate is in the hold mode, to give the ADC a stable input signal.

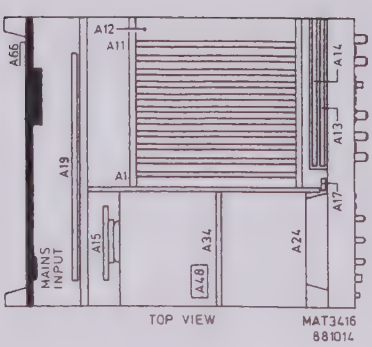
The ADC output lines ADOT00...ADOT10 are led to the overflow detection circuit and to the sample data latch.
Line ADOT11 is buffered by D607. The three buffered lines ADOT11-1...ADOT11-3 are led to the overflow detection and the code converter.

The overflow detection detects whether all 11 ADC output signals are "0" (sample voltage too negative) or "1" (sample voltage too positive). The outputs (wired or) generate via D609 (pin 12 and 9) the OFAD signal to the DPU (unit A9) to indicate that an overflow occured uring the conversion.

The code converter inverts ADOT11-3 (MSB) to convert the ADC output from straight binary code to two´s complement code.
This two´s complement code is latched by the sample data latch and afterwards applied to the DPU by the OTDIAD signal from the DPU.

The ADC logic generates the control signals from the UPCK16 signal. Figure 8.11.1 shows the timing diagram.

UNIT A66 - ASSY FRAME REAR



CONTENTS

8.66.1 Description..... 8.66-1
8.66.2 Signal name list..... 8.66-1

8.66.1 Description

The assy frame rear module consists of a rear plate on which the following parts are mounted:

- power 2 unit (A20)
- mains entrance with fuseholder and fuse
- mains switch
- fan
- battery pack
- several input/output connectors

The circuit diagram can be found in the drawings of the power 1 unit (A19) and the power 2 unit (A20). It needs no further explanation.

WARNING: To avoid any electrical shock, it is strongly recommended to read section 10.1 first.

The rear plate is connected to the chassis of the oscilloscope with an earth cable. For security this cable should never be removed when the rear plate is taken away from the chassis.

ADJUSTING PROCEDURE

ADJUSTING PROCEDURE

CONTENTS

9.0 Adjusting procedure..... 9-1
9.1 General information..... 9-1
9.2 Recommended test and calibration equipment..... 9-1
9.3 Adjusting procedure..... 9-2

Before any adjustment, the instrument must attain ...
operating temperature.

- Warming-up time under average conditions is 30 minutes.
- Where possible, the instrument performance should be checked before any adjustment is made.
- All limits and tolerances given in this section are calibration guides, and should not be interpreted as instrument specifications unless they are also published in chapter 3.
- Tolerances given are for the instrument under test and do not include test equipment error.
- The most accurate display adjustments are made with a stable, well-focussed low intensity display.
- All controls which are mentioned without item numbers are located on the outside of the instrument.

WARNING: The opening of covers or removal of parts, except those to which access can be gained by hand, is likely to expose live parts, and also accessible terminals may be live. The instrument shall be disconnected from all voltage sources before any adjustment, replacement or maintenance and repair during which the instrument will be opened. If afterwards any adjustment, maintenance or repair of the opened instrument under voltage is inevitable, it shall be carried out only by a qualified person who is aware of the hazard involved. Bear in mind that capacitors inside the instrument may still be charged even if the instrument has been separated from all voltage sources.

9.2. RECOMMENDED TEST AND CALIBRATION EQUIPMENT

A complete list of all material necessary for both this adjusting procedure and the performance check is given in chapter 13.1 in this manual.

... are given in figure 9.8
... adjustment step the itemnumber of the
... element (e.g. R4607) and the unit where it is located
(e.g. A20) are given.

NOTE: Use always an isolated adjustment tool.

9.3.2 Power supply adjustments

- Connect a digital voltmeter between the measuring points X4609 and X4611 on unit A20.
- Check for a d.c. voltage of 10 V (+ or - 0,1V). If necessary readjust R4607 on unit A20.
- Connect a digital voltmeter between the measuring points X2517/X2518 on unit A25.
- Check for a d.c. voltage of 5 V (+ or - 100 mV). If necessary readjust R462 on unit A25.

9.3.3 Adjustments in the C.R.T.-section

NOTE: In case that your instrument is completely misadjusted or after exchange of unit A1 it is recommended to turn R2658, R2659, R2678 and R2682 on unit A1 completely counter-clockwise. Moreover it may be necessary to focus the C.R.T. text by means of R2609 on unit A1 and R2832 on unit A15, until it is readable. It may also be necessary to position the C.R.T. text by means of R2513 (vertical gain), R2533 (vertical position), R2566 (horizontal gain) and R2571 (horizontal position) on unit A1.

Switch-on the service menu. Select CHECK & ADJ and then DISPLAY to initiate the menu DISPLAY 0.

Intensity adjustment:

- Turn the knobs INTENS TRACE and INTENS TEXT 90 degrees from their counterclockwise stop.
- Adjust R2637 on unit A1 so that the pattern and the text are just visible.

Focus and astigmatism:

- Put controls FOCUS, INTENS TRACE and INTENS TEXT in their mid position.
- Adjust R2609 on unit A1 (focus) and R2832 on unit A15 (astigmatism) for a sharp and well-defined test pattern. Check also that the points are exactly round; also during changes in the INTENSITY setting.

- Now the display switches ...
  figure 9.1.
  Adjust R2334 on unit A2 so that the vertical jump of the small horizontal lines (marked with a and b in figure 9.1) is minimal (max. allowed jump 0,1 div).

Variable horizontal gain balance:

- Select service menu DISPLAY 2 by depressing softkey NEXT one time.
- Adjust R2377 on unit A2 so that the horizontal jump of the dot in centre of the screen is minimal (max. allowed jump 0,1 div).

Compensation of C.R.T.-tolerances:

- Select service menu DISPLAY 3 by depressing softkey NEXT one time.
- Adjust R2571 on unit A1 so that the horizontal position of the dot is in the centre of the screen (max. deviation 0,1 div).
- Adjust R2533 on unit A1 so that the vertical position of the dot is in the centre of the screen (max. deviation 0,1 div).

Vertical Gain:

- Select service menu DISPLAY 4 by depressing softkey NEXT one time.
- Adjust the Yx5 gain R2531 on unit A1 so that the vertical distance between the two horizontal lines is 8 div (max. deviation 0,1 div).

- Select service menu DISPLAY 5 by depressing softkey NEXT one time.
- Adjust the Yx1 gain R2513 on unit A1 so that the vertical distance between the two horizontal lines (c and d in figure 9.1) is 8 div (max. deviation 0,1 div).

- Select service menu DISPLAY 6 by depressing softkey NEXT one time.
- Adjust the Y/5 gain R2516 on unit A1 so that the vertical distance between the two horizontal lines (a and b in figure 9.1) is 8 div (max. deviation 0,1 div).

Horizontal gain:

- Select service menu DISPLAY 5 by depressing PREVIOUS on time.
- Adjust the horizontal gain R2566 on unit A1 so that the distance between the starting points of the small horizontal lines a and b in figure 9.1 is 10 div (max. deviation 0,1 div).

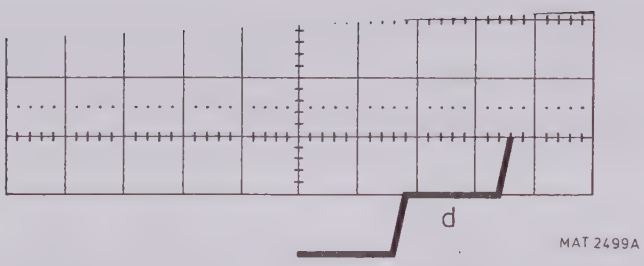


Figure 9.1 Service menu DISPLAY 5.

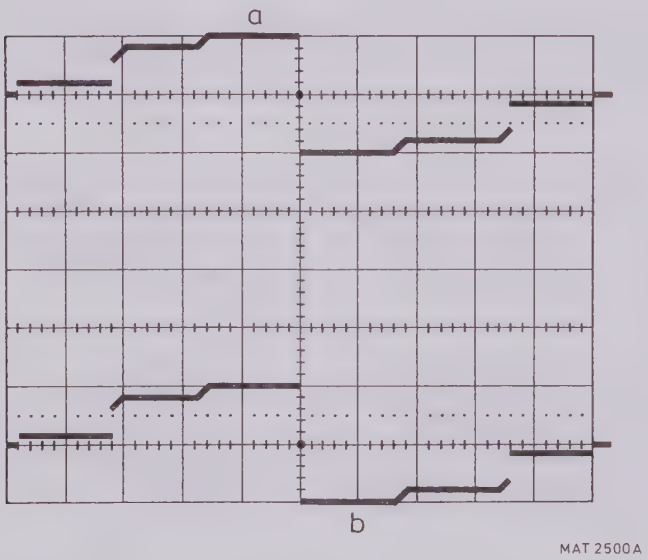

Figure 9.2 Service menu DISPLAY 6.

Overscan suppression:

- Select service menu DISPLAY 7 by depressing softkey NEXT two times.
- Now the pattern of figure 9.3 appears.
- Adjust R2678 on unit A1 so that the test pattern in the left-hand side of the screen is just at its biggest.
- Adjust R2682 on unit A1 so that the test pattern in the right-hand side of the screen is just at its biggest.
- Adjust R2658 on unit A1 so that the test pattern in the bottom side of the screen lies 0,1 div outside the graticule of the screen.
- Adjust R2659 on unit A1 so that the test pattern in the top side of the screen lies 0,1 div outside of the graticule of the screen.
- Now leave the service menu by depressing AUTO SET.

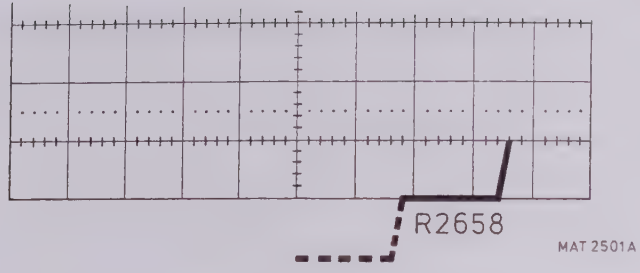

Figure 9.3 Service menu DISPLAY 7.

9.3.5 Adjustment of the frequency doubler:

- Connect a digital d.c. voltmeter between measuring point X8701 on unit A48 and ground (pin 1 of unit A48).
- Set the time-base at 500 ns/div.
- Adjust the voltage at the maximum negative level with C8703 on unit A48.
- Set the time-base at 100 ns/div.
- Adjust the voltage at the maximum negative level with C8702 on unit A48.
- Set the time-base at 500 ns/div.
- Re-adjust the voltage at the maximum negative level with C8703 on unit A48.

9.3.6 P^2CCD pre-adjustment

NOTE: The now following steps must only be done if the instrument is completely misadjusted or after replacement of unit A33.

- Press AUTO SET.
- Set the time-base at 200 us/div.

Jump DIRECT/P^2CCD-mode:

- Connect measuring point X3347 with the ground measuring point X3358 on unit A33.
- Adjust the trace in the mid of the screen with the YPOS control.
- Set the time-base at 500 us/div.
- Adjust the trace in the mid of the screen with R705 on unit A11 (Attainable via side panel).
- Set the time-base at 200 us/div.
- Disconnect the link between measuring point X3347 with ground measuring point X3358.
- Apply a triangular signal of 1kHz/600 mV (pp) to Ch. A and Ch. B.
- Select 100 us/div. 100 mV/div for Ch. A. and Ch. B.

Reference voltage P²CCD gain:

- Connect a digital d.c. voltmeter between measuring point X3343 and the ground measuring point X3358 on unit A33.
- Adjust the voltage to -300 mV (+ or - 20 mV) with R8326. The polarity of X3343 is negative with respect to ground!

BIAS charge:

- Measure the voltage at X3341 (X3348 for ch. B) on unit A33 with a measuring oscilloscope (AC input coupling, 2 ms/div) that is triggered on signal TDUF-2 (X2631 on unit A26).
- Adjust R7939 (R8139 for ch. B) so that the distance between level a and b during the correction stroke in figure 9.4 is 300 mV (+ or - 20 mV).

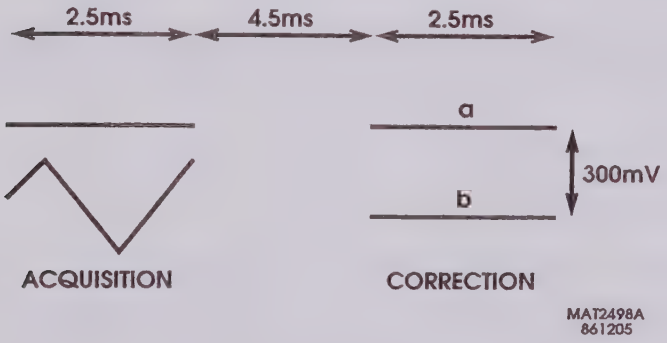

Figure 9.4 Voltage-waveform present at X3341 and X3348.

Pre-adjustment of P²CCD output circuits:

NOTE: The now following steps must only be done if the instrument is completely misadjusted or after replacement of unit A33.

- Put the potentiometers R8419, R8421...R8424, R8426...R8429, R8434, R8436, R8441...R8444, R8446...R8449, R8451 on unit A33 in their mid position.
- Connect the input of the measuring oscilloscope (DC-coupled) with measuring point X3347 on unit A33. The oscilloscope must remain triggered on measuring point TDUF-2 X2631 on unit A26.
- Adjusting of R8419, R8434, R8436 and R8451 on unit A33 influences each a level during the correction stroke. Adjust these four levels to 0 V with these potentiometers.

- Disconnect the measuring oscilloscope and the input signals.

9.3.7 Adjustment of the CORRECTION CIRCUIT (R721).

- Press AUTO SET.
- Select 50 ohm input impedance for channel A.
- Set the input sensitivity at 500 mV/div for both channels.
- Set the time-base at 5 us/div.
- Apply a sine-wave signal with a frequency of 500 kHz and an amplitude of 2 div at channel A.
- Select Average C=4 (VERTICAL MODE - PROCESSING - AVERAGE - C=4).
- Select Peak-Peak measurement (CURSOR/ANALYZE - ON - MEASURE - AMPLITUDE - PEAK).
  1 Position the top of the signal at the top horizontal graticule line with the SHIFT control.
  2 Adjust the amplitude of the generator to 1,05 V peak-peak (+ or - 10 mV) as indicated by the Peak-Peak measurement.
  3 Position the bottom of the signal at the bottom graticule line with the SHIFT control.
  4 Adjust the amplitude to 1,05 V (+ or - 0,01 V) with R721 on A11.
- Repeat the steps 1 to 4 until no more adjustments are needed.
- Check the same (steps 1 to 4) for channel B.
- If the deviation between channel A and B is more than 0,05 div. then the difference must be averaged between both channels.
  eg: Channel A = 1,05 and channel B results in 1,23. Then adjust channel A to 0,96 and check that channel B = 1,14
- Disconnect the input signals.
- Press AUTO SET.

- Apply a calibrated square-wave signal of 2 V/1 kHz to channel A and B and press AUTO.
- Select DC input coupling for Ch. A and B and an input sensitivity of 500 mV/div. Both channels in CAL position.
- Set the time base to 2 ms/div.
- Select ADD mode and B-INVERT via MODE.
- Adjust R5102 on unit A32 for minimal signal display (max. 0,1 div).
- Switch B-INVERT off.
- Disconnect the input signals.

Gain and offset adjustment of P^2CCD output circuits and adjustment of offset single/dual channel:

NOTE: The following adjustments are described for channel A first. The reference numbers for channel B are given between brackets.

- Apply a calibrated square wave signal of 2 V(pp), 1 kHz to the channel A (B) input.
- Switch-on the service menu. Select CHECK & ADJ and then P2CCD A (P2CCD B). The menu P2CCD A Ø (P2CCD B Ø) appears.
- Adjust the trace on the vertical mid of the screen with the frontpanel SHIFT A (SHIFT B) control.
- Depress softkey NEXT to reach service menu P2CCD A 1 (P2CCD B 1).
- Adjust the trace symmetrically around the vertical mid of the screen with R8419 (R8436) on unit A33.
- Adjust the gain (4 div) with R8421 (R8441) on unit A33.
- Depress softkey NEXT to reach service menu P2CCD A 2 (P2CCD B 2).
- Adjust R8434 (R8451) on unit A33, to a minimal jump of the trace (max. allowed jump 0,1 div).
- Depress softkey NEXT to reach service menu P2CCD A 3 (P2CCD B 3).
- If the adjustment is incorrect, the screen shows a square wave with spikes. Adjust with R8426 (R8446) on unit A33 the amplitude of the square wave to minimal (max. amp. 0,1 div).
- Depress softkey NEXT to reach service menu P2CCD A 4 (P2CCD B 4).
- Adjust R8434 (R8451) on unit A33 again to a minimal jump of the trace (max. allowed jump 0,1 div).
- Depress softkey NEXT to reach service menu P2CCD A 5 (P2CCD B 5).
- Adjust the gain (4 div) with R8422 (R8442) on unit A33.

- Increase the frequency of the input signal.
- Adjust the gain (6 div) with R8424 (R8444).
- Depress softkey NEXT to reach service menu P2CCD A 10 (P2CCD B 10).
- Adjust the gain (6 div) with R8429 (R8449).
- Depress softkey NEXT to reach service menu P2CCD A 11 (P2CCD B 11).
- Adjust the gain (6 div) with R8427 (R8447).
- Depress softkey NEXT to reach service menu P2CCD A 12 (P2CCD B 12).
- Disconnect the input signal.
- Adjust R7515 (R7715) to a minimal jump of the trace (max. allowed jump 0,1 div).

- Repeat the steps above, but now for channel B.

- Remove the input signals.

Gain 5 V/div.:

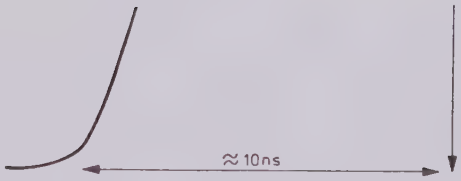
- Apply a calibrated square-wave of 20 V/1 kHz to inputs A and B.
- Press AUTO SET.
- Select DC input coupling for Ch. A and B.
- Check 5 V/div. input sensitivity for Ch. A and B.
- Adjust R5046 on unit A32 (Ch. A) and R5146 on unit A32 (Ch. B) to a vertical deflection of 4 div (max. deviation + or - 0,1 div).
- Remove the input signals.

Offset dual/add:

- Set with shift A and B both traces to the vertical mid of screen
- Select display mode ADD via MODE.
- Adjust the trace in the vertical mid of the screen with R7612 on unit A33.

Offset and gain MIN / MAX and P^2CCD mode:

- Switch on the service menu. Select CHECK & ADJ and then the menu VERTICAL.
- Depress softkey NEXT two times to reach service menu VERTICAL 2. The instrument now switches between MIN/MAX mode on and off.
  When MIN / MAX mode is off, two intensified traces are visible, one for each channel.
  If the adjustment is incorrect each channel shows 2 low intensity traces (when MIN/MAX is on).
- Adjusting of R7566 on unit A33 (P7766 for Ch. B) influences the position of one of these low intensity traces.
  Adjust this trace on the same position as the intensified trace (max. allowed jump 0,1 div.).



MAT2502A
861205

Figure 9.5 HF-pulse response.

9.3.10 Delta-t adjustment:

- Select the DOTS mode.
- Apply a 50 MHz sine-wave signal to Ch. A.
- Depress AUTO SET.
- Adjust the generator to a sine-wave amplitude to 6 div.
- Set the time base in position 5 ns/div.
- Adjust R8607 on unit A34 so that a continuous smooth sine-wave signal is displayed.
- Depress WRITE and check if the displayed sine-wave stays without discontinuities.
- Select 1 Mohm input impedance for ch. A and B.

9.3.11 Triggering

AC/DC balance EXT TRIG input:

- Apply a 100 Hz/600 mV sine-wave to inputs Ch. A and EXT TRIG.
- Switch-on the service menu. Select CHECK & ADJ and then the menu TRIGGER Ø.
- Adjust R7022 on unit A32 so that the trigger point does not shift (max. allowed shift 0,1 div).

AC/DC balance internal triggering via Ch. A and B:

- Depress softkey NEXT in order to come in the service menu TRIGGER 1.
- Apply a 100 Hz/600 mV sine-wave signal to Ch. A and Ch. B.
- Adjust R5030 on unit A33 so that the trigger point does not shift (max. allowed shift 0,1 div).
- Depress softkey NEXT in order to come in the service menu TRIGGER 2.
- Adjust R5130 on unit A33 so that the trigger point does not shift (max. allowed shift 0,1 div).

- Apply a 100 Hz/120 mV (pp) sine-wave signal to Ch. A.
- Put R7046 on unit A32 fully counterclockwise.
- Adjust R7084 on unit A32 so that the trigger gap lies exactly in the mid between the top and the bottom level of the signal.
- Decrease the generator output signal to 0,4 div.
- Adjust R7156 on unit A32 to a correctly triggered display.
- Increase the signal amplitude to 6 div.
- Check that the trigger point lies exactly in the mid between the top and the bottom level of the signal (max. allowed deviation + or - 0,1 div). If not readjust R7084 and R7156.

LEVEL sensitivity:

NOTE: This adjustment is also done with the use of service menu TRIGGER 4.

- Decrease the generator output signal to 0,4 div.
- Adjust R7046 on unit A32 so that the signal is just triggered.

AUTO/DC balance:

- Apply a 100 Hz/600 mV (pp) sine-wave to Ch. A.
- Depress softkey NEXT in order to come in the service menu TRIGGER 5.
- Adjust R7036 on unit A32 so that the trigger point does not shift (max. allowed shift 0,1 div).

Adjustment of dual triggering:

- Depress softkey NEXT in order to come in the service menu TRIGGER 6.
- Apply a sine-wave signal of 6 div (pp) and a frequency of 100 Hz approx. Adjust the frequency so that the trigger slope flashes between positive and negative triggering.
- Adjust the gap between positive and negative slope to a minimal value with R7116 on unit A32.
- Adjust the vertical symmetry between positive and negative slope with R7129 on unit A32 (max. allowed deviation + or - 0,1 div).

[illegible] (around vertical mid of screen).
Max allowed deviation + or - 0,1 div.

NOTE: If necessary re-adjust R2533 on unit A1 by using service menu DISPLAY 3, so that the vertical position of the dot is in the centre of the screen (max. deviation 0,1 div).

- Depress AUTO SET.

LF square-wave response EXT and EVENTS inputs:

- Apply a square-wave signal of 10 kHz/3 V to input EXT TRIG.
- Select EXT as trigger source.
- Connect the probe of a measuring oscilloscope to pin 1 of mini unit A40 (on unit A32).
- Adjust R4751 on unit A31 to a straight pulse top.
- Increase the generator's square-wave amplitude to 30 V.
- Select EXT:10 as trigger source.
- Adjust R4753 on unit A31 to a straight pulse top.
- Apply a square-wave signal of 10 kHz/3 V to input EVENTS.
- Connect the probe of the measuring oscilloscope to pin 1 of mini unit A43 (on unit A32).
- Adjust R4851 on unit A31 to a straight pulse top.

NOTE: R4853 on unit A31 needs no adjustment.

AUTO offset level:

- Apply a sine-wave voltage 1 kHz/100 mV to Ch. A.
- Press AUTO SET.
- Select 100 mV/div for Ch. A.
- Adjust R7052 on unit A32 so that the voltage at measuring point X7007 on unit A32 is 0 V (max. allowed deviation 100 mV). Voltage must be measured with a digital multimeter (d.c. voltage range).

9.3.12 Output voltage calibration generator:

The amplitude of the calibration signal must lay between 0 and +1 Volt. This must result in a read-out of 500 mV on a digital a.c.-r.m.s. or d.c. millivoltmeter since the duty cycle of the signal is 50%. If not, re-adjust R2703 on unit A1.

right in the bottom of the screen.

- Measure with a digital multimeter (d.c. voltage range) the maximum voltage at the vertical plot output (red banana plug, black is mass). This voltage must be adjusted to 1000 mV by means of R2738 on unit A1.
- Measure with a digital multimeter (d.c. voltage range) the maximum voltage at the horizontal plot output (blue banana plug, black is mass). This voltage must be adjusted to 1000mV by means of R2728 on unit A1.
- Select 20 ms/DT via the menus PLOT, SELECT and ANALOG.
- Press AUTO SET.

9.3.14 Fan Check

- Check that the fan runs.
- Measure the d.c. voltage between X4611 and the positive pole of capacitor C4629 on unit A20 with a digital voltmeter. This voltage should be higher than 16 V.

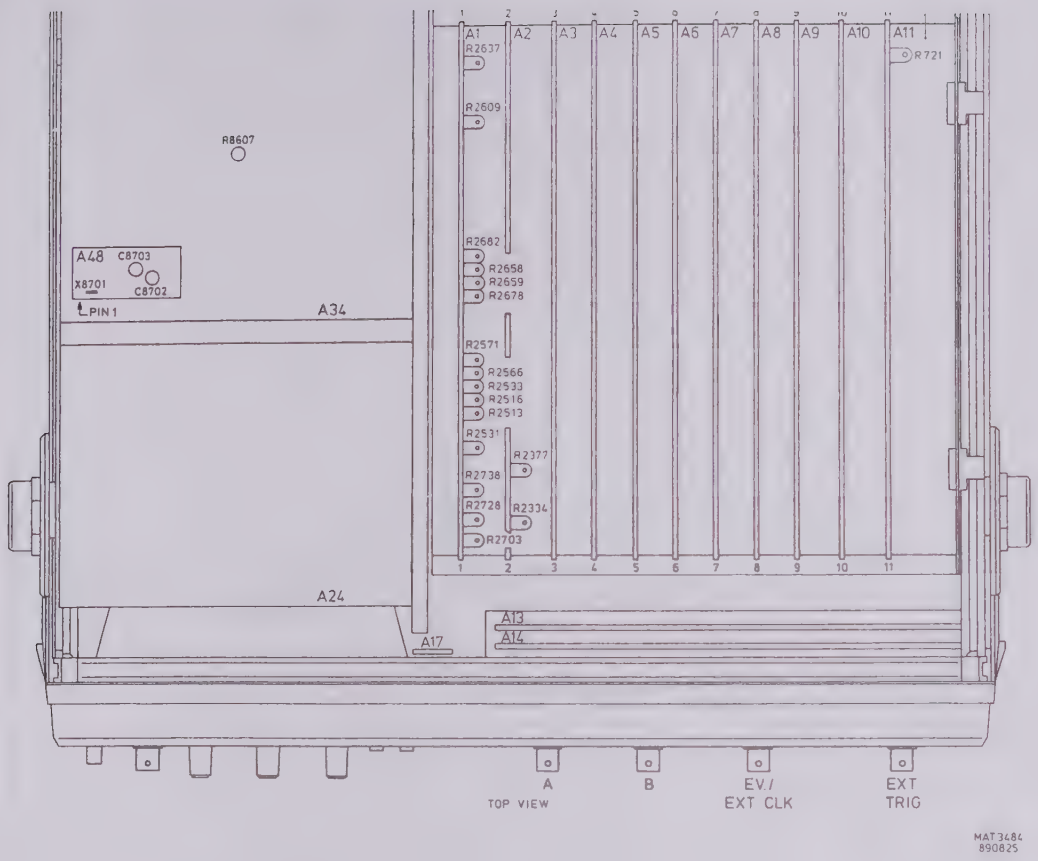


Figure 9.6 Position of adjusting elements - top side.

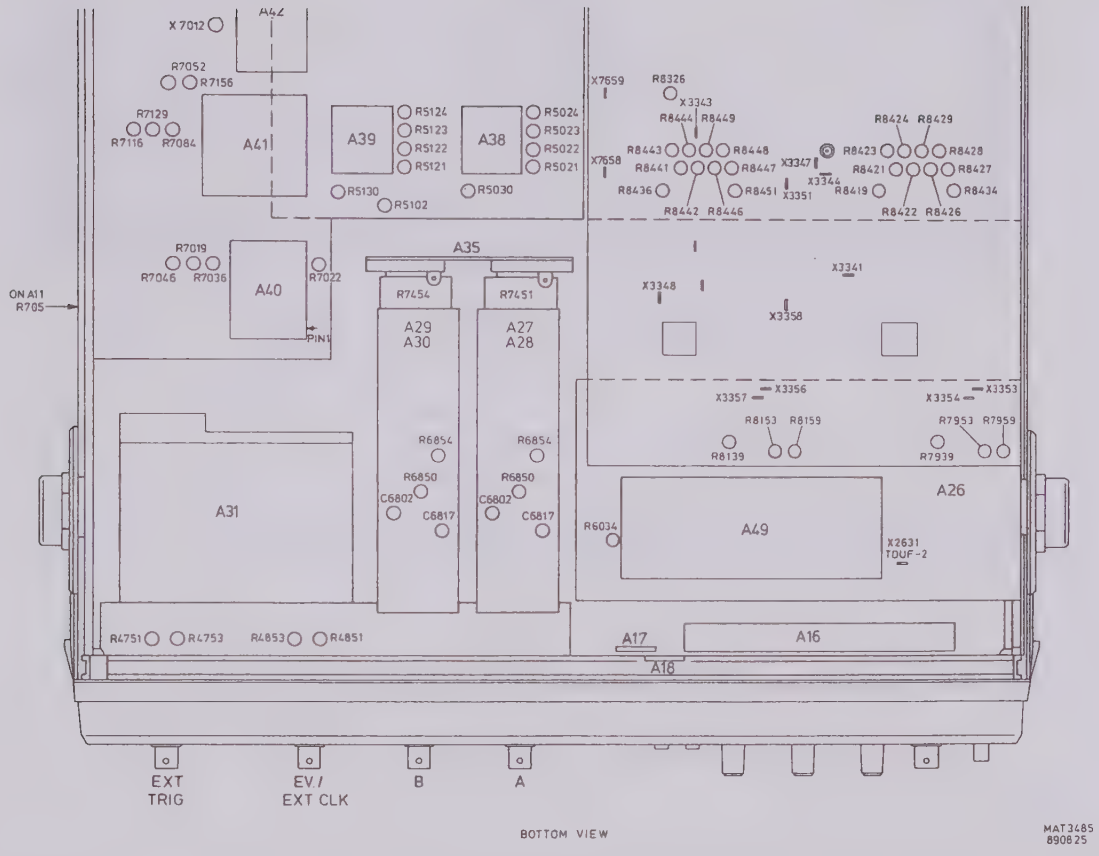

Figure 9.7 Position of adjusting elements - bottom side.

10.7.1	Removing the complete front unit	10-9
10.7.2	Removing the knobs of the rotary controls	10-10
10.7.3	Removing the textplate	10-10
10.8	Removing the C.R.T. control unit	10-10
10.9	Removing the softkey unit	10-10
10.10	Removing and installing the cathode ray tube	10-11
10.11	Removing the carrying handle	10-12

10.0 DISASSEMBLING AND ASSEMBLING

10.1 REMOVING THE INSTRUMENT COVERS

See chapter 5, section 5.2.

WARNING: The opening of the covers exposed live parts and also accessible terminals may be live.
The instrument shall be disconnected from all voltage sources before any replacement or maintenance or repair, during which the instrument will be opened.
Capacitors inside the instrument may still be charged, even if the instrument has been separated from all voltage sources.

To avoid shocks the high voltage capacitor C4616 on POWER 2 unit A20 at the inner side of the rear panel has to be discharged. This can be done by connecting a 1 Mohm resistor from the node of capacitor C4616 and the EHT transformer D4601 to the chassis of the oscilloscope. This node is marked with an X in figure 10.1.

The E.H.T. cable is permanently connected to the E.H.T. unit (disconnection at C.R.T.).
When the E.H.T. cable to the post-acceleration anode of the C.R.T. is disconnected at the C.R.T. end, the E.H.T. cable must be discharged immediately by shortening it to the chassis of the oscilloscope.

10.2 REPLACEMENTS

Standard parts

Electrical and mechanical replacement parts can be obtained through your local Philips organisation or representative. However, many of the standard electronic components can be obtained from other local suppliers.
Before purchasing or ordering replacement parts, check the parts list for value tolerance, rating and description.

NOTE: Physical size and shape of a component may affect instrument performance, particularly at high frequencies. Always use direct-replacement components, unless it is known that a substitute will not degrade instrument performance.

Special parts

In addition to the standard electronic components, some special components are used.
These components are manufactured or selected by Philips to meet specific performance requirements.

Transistors and integrated circuits

Transistors and integrated circuits should not be replaced unless they are actually defective. If removed from their sockets during routine maintenance return them to their original sockets. Unnecessary replacement or switching of semiconductor devices may affect the calibration of the instrument.
When a transistor is replaced, check the operation of the part of the instrument that may be affected.

WARNING: Handle silicone grease with care. Avoid getting silicone grease in the eyes. Wash hands thoroughly after use.

Any replacement component should be of the original type or a direct replacement. Bend the leads to fit the socket and cut the leads to the same length as on the component being replaced.

10.3 REMOVING THE PLUG-IN PRINTED CIRCUIT BOARDS

The plug-in boards are:

A1 Final amplifier
A2 Display dac
A3 Display control
A4 Display memory
A5 MRAM + ACL
A6 UP board
A7 Option
A8 DPU control
A9 DPU
A10 Option
A11 ADC + T&H

These plug-in units can easily be removed (after removing the bracket and the various cables) with the aid of the red handles.

If a plug-in board is removed it can be placed on an extension board to do measurements.
For more information about the extension board see section 13.3.4.

WARNING: The plug-in boards have to be replaced at the correct locations to prevent damage.

10.4 REMOVING AND MOUNTING THE REAR PANEL

- Take security measures (see section 10.1).
- Remove 4 screws marked with A in figure 10.1.
- Remove 4 opposite screws at the bottom side.

WARNING: If the screws are removed the oscilloscope may not stand on its rear side.

- Remove 2 screws marked with B.
- Remove the remaining opposite screw at the bottom side.
- Remove 4 nuts (2 on each side) with washers, marked with C.
- Slacken 4 screws (2 on each side) marked with D a few turns.
- Slacken the screws of the fixation points of the E.H.T. cable to the C.R.T.
- Disconnect the analog plot out cable on unit A1.
- Pull the rear panel out of the oscilloscope and lay it down, thereby shifting through the E.H.T. cable and the analog plot out cable.

In this situation the oscilloscope can operate and measurements can be done.
Because connector X4604 of unit A20 is disconnected, the high voltage is not present, so nothing can be seen on the screen.
Also the power supply is not fully loaded, because the management unit A25 is not connected.
To test the power supply under full load, the extension board for the plug in units can be used as shown in figure 10.2.
It is also possible to use a dummy load, which is specified in section 13.2.

WARNING: If the osciloscope is operating, parts of POWER 1 unit A19 are at mains potential.

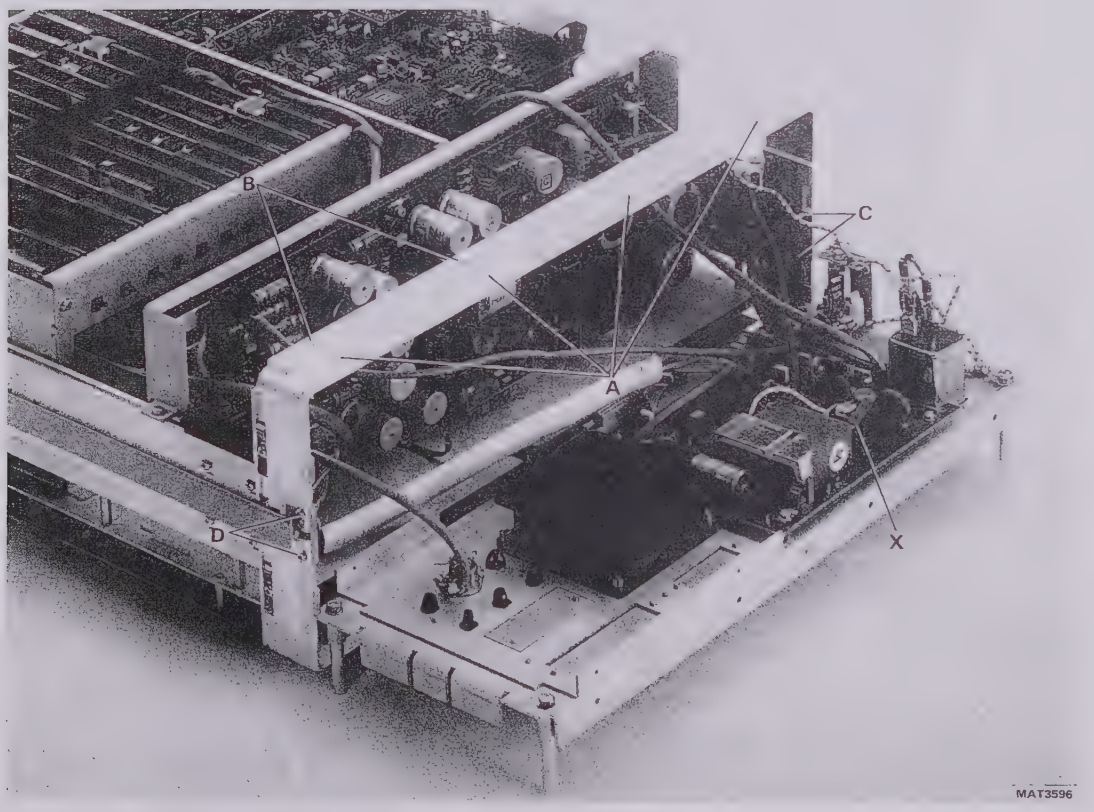

Figure 10.1 Removing the rear panel.

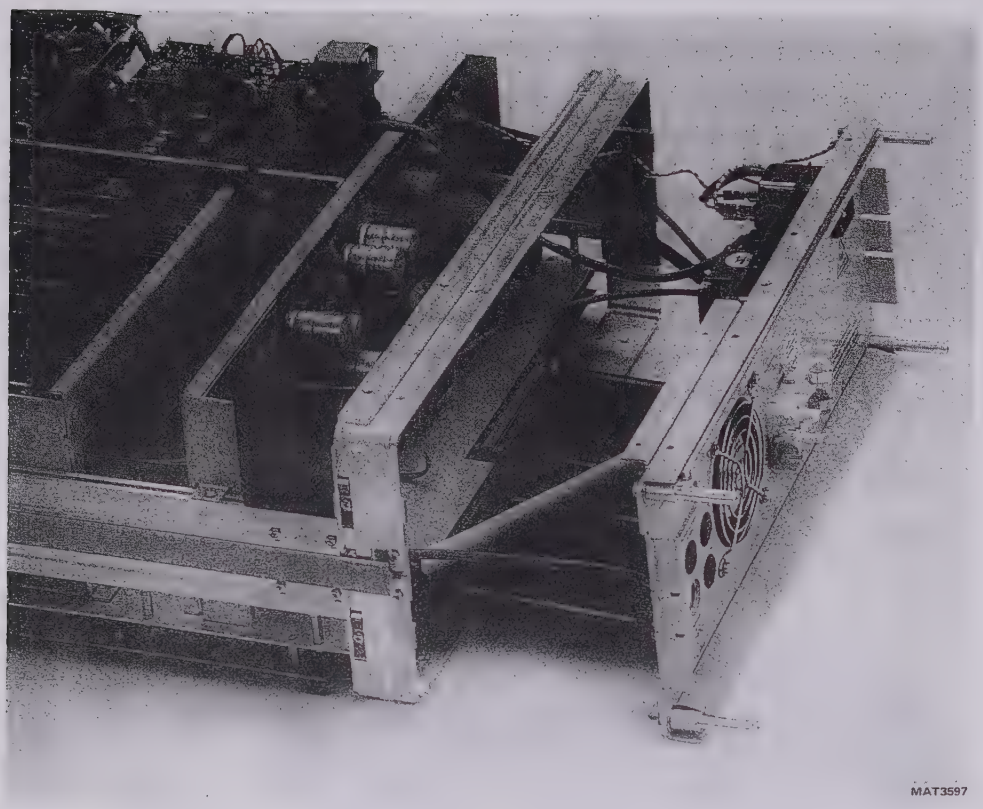

Figure 10.2 Use of the extension board for the rear panel.

To reinstall the rear panel the above mentioned steps have to be done in reverse order.

Special attention is asked for:

- The cable from the mains switch to connector X4401 on unit A19 has to be positioned as much as possible between capacitors C4416 + C4417 and the side of the oscilloscope, to pick up as less interference as possible from transformer T4401.
- The high voltage cable from the E.H.T. transformer should not touch transistor V4612.

10.5 ACCESS TO THE MANAGEMENT UNIT AND THE CCD LOGIC UNIT

To get access to the management unit A25 and the CCD logic unit A26 the P^2CCD unit A33 and the vertical signal unit A32 can be turned up as shown in figure 10.3.

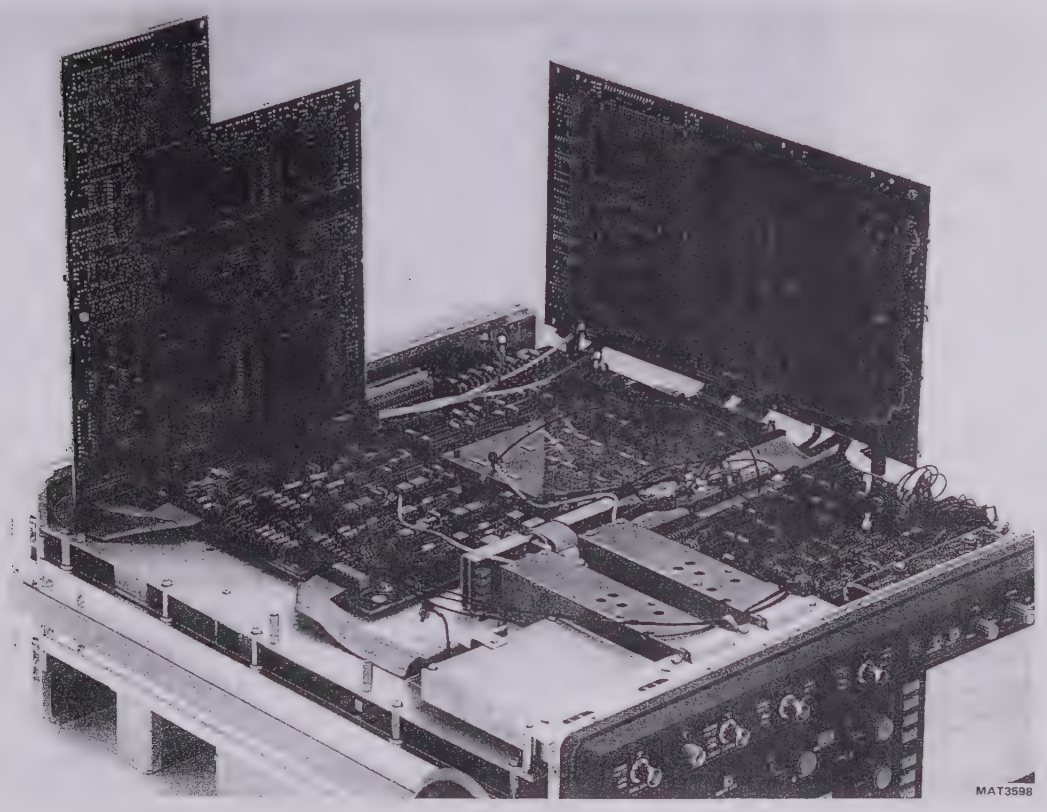

Figure 10.3 Access to the management unit and the CCD logic unit.

The vertical signal unit can be turned up as follows (see figure 10.4):

- Disconnect all coaxial wiring.
- Remove 2 screws marked with A and remove the profile.
- Remove 2 distance pieces that were below the profile.
- Remove 5 remaining screws.
- Turn the unit up and place it on the two supports as shown in figure 10.3.

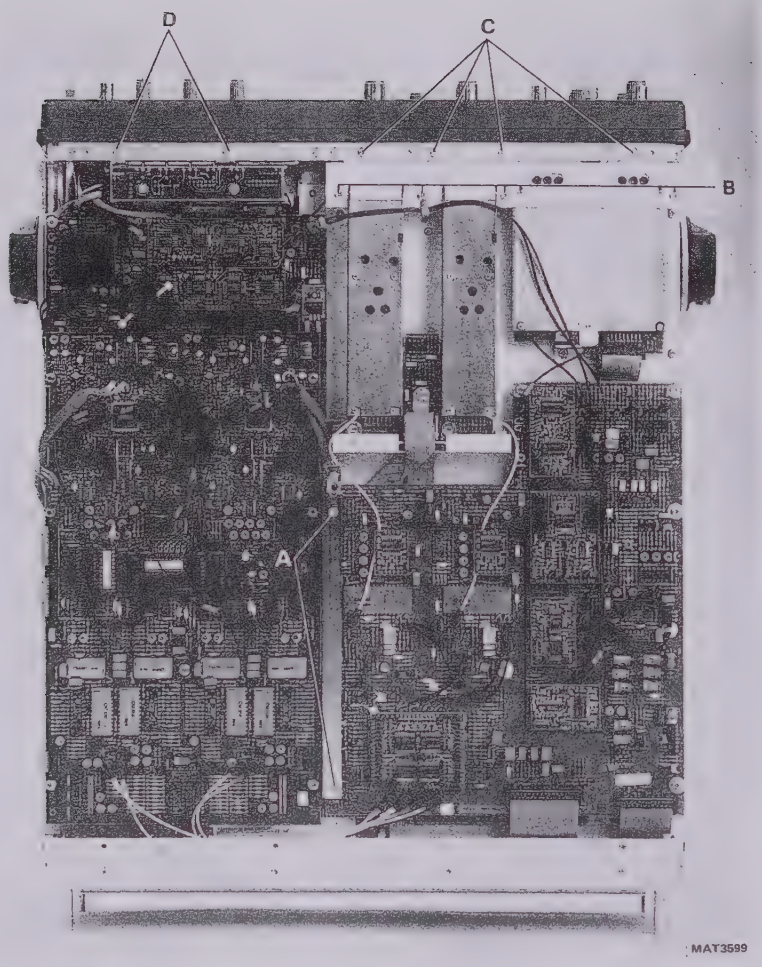

Figure 10.4 Bottom side of the oscilloscope.

The P^2CCD unit can be turned up as follows (see figure 10.4):

- Disconnect all coaxial cables
- Remove 9 screws.
- Turn the unit up and place it on the two supports as shown in figure 10.3.

Now the shielding plate over the management unit, which is fixed with 3 spacers, can be removed.

In this position the oscilloscope can operate, but will not function properly. Nevertheless certain measurements can be done on the units A25 and A26. If longer coaxial cables are used (see section 15.3.2) the instrument can operate completely.
To reinstall the boards the steps have to be done in reverse order. Care should be taken of the reconnection of the coax cables at the right points. The cables should also be repositioned as much as possible to their original positions.
Note that the screw on the corner of the p.c.b. near IC N7913 is equipped with an isolating washer.

NOTE: If one of the coax cables should be replaced care should be taken that the length difference between this cable and cables with similar signals (e.g. balanced signals) is less than 1 cm, to avoid delay time differences.
Coax cables between the driver unit A24 and the P^2CCD unit A33 can only be replaced as a complete set.

10.6 REMOVING THE ADAPTION UNIT, THE OFFSET ADAPTATION UNIT, THE VERTICAL ATTENUATORS AND THE EXTERNAL TRIGGER UNIT

10.6.1 Removing the adaption unit (unit A35) and the offset adaptation unit (unit A50)

- Remove 2 screws marked with A in figure 10.4 and remove the profile.
- Remove the screw and the nylon clamp between the vertical attenuators that locks the flatcable to the offset adaption unit.
- Disconnect the flatcable to the offset adaptation unit.
- Remove the distance piece, that fixes the offset adaption unit and remove the offset adaptation unit.
- Slacken the distance piece between the vertical attenuators that fixes the adaption unit.
- The unit can now be slided backwards and removed from the mounting plate.

10.6.2 Removing the vertical attenuator units

- Remove the offset adaptation unit and the adaption unit (see section 10.6.1).
- Disconnect the coax cables to the vertical signal unit A32.
- Remove 6 screws marked with B in figure 10.4.
- Slacken 4 screws marked with C in figure 10.4.
- The attenuators can be slided backwards and removed.

10.6.3 Disassembling of a vertical attenuator unit.

- Remove the two small screws that fix the shielding case and slide the case from the unit in the direction of the BNC input connector.

NOTES:
- The unit can be measured under operating conditions if it is reconnected to the adaption unit and if all wiring is connected.
- It is strongly recommended to take notice of this chapter and belonging figure 10.5 before starting the job.

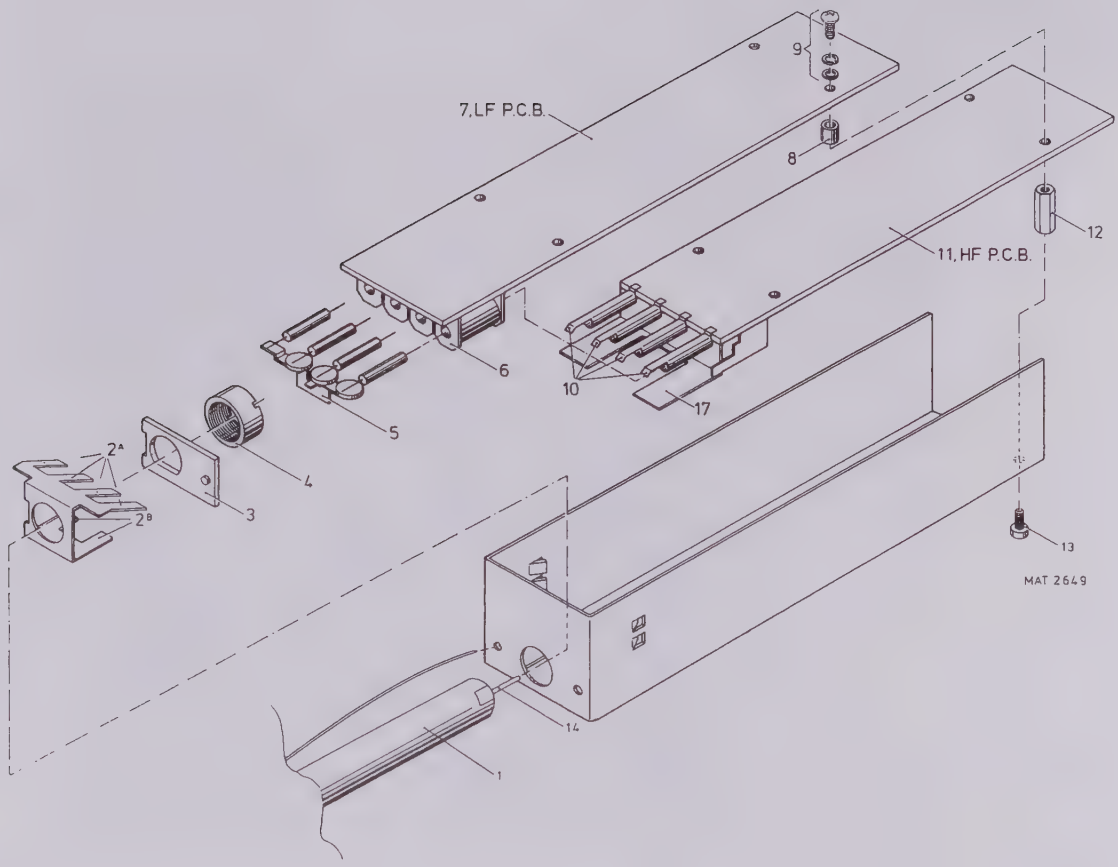

Figure 10.5 Exploded view of attenuator.

- Put the unit on your bench with the LF-p.c.b. upwards.
- Unsolder the wire of the probe detection contact from the soldering tag on the LF-p.c.b.
- Remove the capacitor between the shielding case and the soldering tag on the LF-p.c.b.
- Unsolder the four shielding cans (10) from the tags of the earth bracket (2A).
- Put the unit on your bench with the HF-p.c.b. upwards.
- Unsolder the two tags (2B) of the input earth bracket from earth bracket (17).
- Remove two screws (13) that attach the p.c.b.´s to their mounting bracket.
- Put the unit on your bench with the HF-.p.c.b. upwards and unsolder the signal tag (14) from the bracket with the input capacitors (5). This must be done very quickly in order to avoid that the input capacitors are overheated.
- The subassembly consisting of the LF and HF p.c.b. can be slided out of the mounting bracket.

NOTE: After the above actions, the 50 Ohm termination resistor array on the HF-p.c.b. can be interchanged.

- The BNC-socket can be separated together with the tube and the probe detection contact from the bracket with a special tool that fits on the slotted nut (4) of the tube. More information about this tool is given in section 13.3.1. Together with the removal of the tube the separate parts 2,3 and 4 can be taken apart.

- If you want to separate the HF (11) and LF (7) p.c.b.´s, it is necessary to remove the glass reed switches from their coils. For this purpose the bracket with the input capacitors (5) must be unsoldered from the reed relays. After this the other side of the reed relay can be unsoldered from the HF-p.c.b. and it can be slided out of the coil. Also the resistor between the bracket and the LF-p.c.b. must be unsoldered at the LF-p.c.b. Now the hardware (4x) that fixes the HF and LF p.c.b. together (9,8,12) can be removed and the HF-p.c.b. (11) with its four shielding cans (10) can be slided out of the reed relay coils (6) on the LF-p.c.b. (7).

10.6.4 Removing the external trigger unit

- Remove the electrical wiring to the unit.
- Remove the support next to the flatcable connector.
- Remove 6 screws marked with B in figure 10.4.
- Slacken 4 screws marked with C in figure 10.4.
- The unit can be slided backwards and removed.
- To disassemble the unit, remove the three remaining small screws, remove the bracket and slide the shielding case from the unit.

10.7 REMOVING THE FRONT UNIT

10.7.1 Removing the complete front unit

- Remove 3 screws marked with A (see figure 10.6).
- Slacken 3 screws marked with B.
- Slacken 2 screws marked with C.
- Carefully press the front unit via the front side out of the instrument.
- Disconnect the two flatcable connectors from the front unit.
- Now the front unit itself can be disassembled easily.

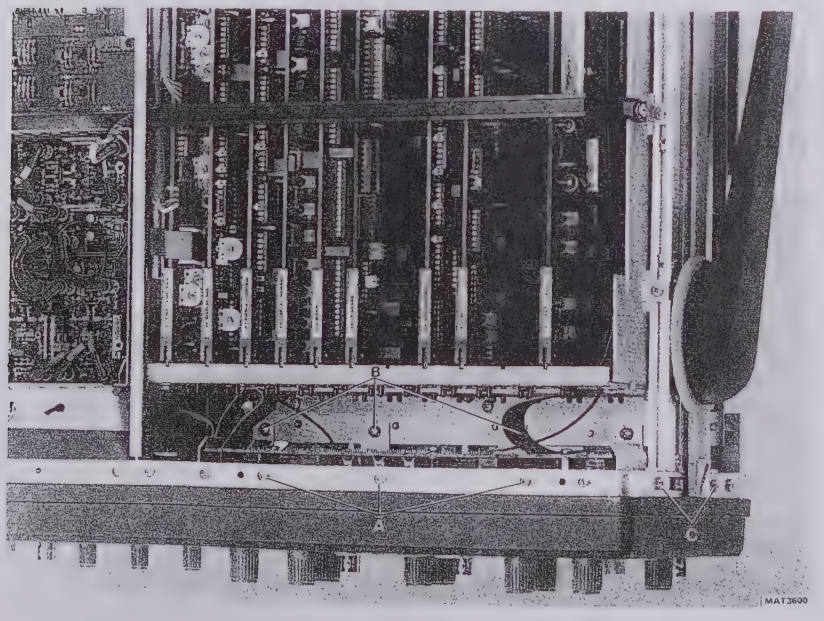

Figure 10.6 Removing the front unit.

10.7.2 Removing the knobs of the rotary controls

- Remove the knob cover.
- Slacken the internal nut.
- Pull off the knob.

10.7.3 Removing the textplate

- Remove the complete front unit as described in section 10.7.1.
- Remove all the knobs of the rotary controls (see section 10.7.2).
- Remove 5 slotted nuts which fix the textplate and the aluminium housing to the unit. This can be done with a special tool for slotted nuts as described under section 13.3.1.
- Remove the textplate.

NOTE: For a repair of a defective rotary control the textplate has not to be removed. Only the p.c.b. with the leds and the fototransistors (unit A14) has to be removed then.

10.8 REMOVING THE C.R.T. CONTROL UNIT (A16 + A18)

- Turn unit A33 up as described in section 10.5.
- Remove the fixation screws of unit A26 and shift the unit a little backwards.
- Remove the three C.R.T. control knobs as follows:
  - Remove the knob covers.
  - Slacken the internal screws.
  - Pull the knobs off.
- Remove the electrical wiring.
- Remove 2 screws on the front profile marked with D (see figure 10.4) and pull the unit backwards.

NOTE: When reinstalling the unit take care of the correct position of the marks on the caps of the knobs.

10.9 REMOVING THE SOFTKEY UNIT (A17)

- Remove the front unit as described in section 10.7.1 until the unit is from the instrument and remove the bezel with the contrast filter.
- Remove the caps from the softkeys (8x).
- Remove 3 fixation screws of the support of the softkey unit inside the frontpanel hole.
- Remove the support with the softkey unit through the frontpanel hole.
- Remove the softkey unit from the support and disconnect the flatcable.

NOTE: When the unit is re-installed, the middle screw of the support is turned in a small metal bezel support, which might get lost.

TROUBLE SHOOTING AND SERVICE DIAGNOSTICS 11

TROUBLE SHOOTING

CONTENTS

11.0 Trouble shooting..... 11-1
11.1 Introduction..... 11-1
11.2 Trouble shooting techniques..... 11-1
11.3 Trouble shooting hints..... 11-2
11.4 Description of the diagnostic software..... 11-3
11.5 Recalibration after repair..... 11-19

- Connect a signal of 100 Hz 500 mVpp to the disconnected coaxial cable connector. This signal is applied to the ADC unit A11 via the coaxial cable.
- Check that the signal is visible on the C.R.T. with some distortion. The signal is not stable triggered, but changes of frequency, amplitude or waveform should become visible.
- If no traces are visible then check:
    - Trace intensity control
    - Z-control
    - Units A3, A4, A5, A8, A9, A11

- If the traces become visible in the way as described, the fault is in the acquisition section. This is unit A33 or one of the units between the signal inputs and A33 (A27 to A32) or in the units, which control these units (A25, A5, A26, A49, A34, A48).

- If the DPU operates properly, the signal IL$\emptyset$2--LT gives regularly negative pulses.

- If the acquisition operates properly, HDOF--LT on unit A26 gives regularly positive pulses. The rising edge of the pulse is the start of a new acquisition.

- If certain time base settings do not operate properly, the mode overview in section 8.33.3 may give an indication of where the fault is.

11.4 DESCRIPTION OF THE DIAGNOSTIC SOFTWARE

11.4.1 Introduction

The diagnostic software consists of three parts:

- the power up routine
- softkey selectable diagnostic software
- hardware selectable diagnostic software

It is recommended to read the concerning hardware description first (chapter 8), before using the diagnostic software.

Each part will be described in the following subsections.

11.4.2 The power up routine

The power up routine is initiated every time the oscilloscope is turned on or when the microprocessor is restarted by the watchdog circuit (unit A6). It performs the following actions:
- First all leds on the front panel are turned on during 3 seconds.
- The leds REP ONLY and NOT TRIG´D are extinghuished.
  Now the part of the microprocessor RAM (unit A5) which does not contain data that should be retained, is tested. If the test fails, the leds stay off and the address where the failure is, is continuously read and written by the microprocessor. This makes tracing of the failure easier.

- The led REP ONLY is turned on, so only led NOT TRIG´D is off. Now the TEXT MEMORY is tested. The TRACE MEMORY can not be tested, because these data should be retained.
  If the test fails, the led NOT TRIG´D stays off and the address where the failure is, is continuously read and written by the microprocessor, as with the previous test.
- The led NOT TRIG´D is also turned on, so all leds are on.
  Now the part of the microprocessor ram (unit A5) that contains settings, is tested by means of a checksum test.
  If a fault is found in a setting belonging to a stored trace, this setting is cleared.
  If a fault is found in a programmed front setting, the concerning front setting and all front setting which are stored at higher addresses are cleared. Because all settings are stored in time order of entrance, an "arbitrary" part of the settings is cleared.
  Next the actual front setting is checked. If it has a checksum fault an AUTO SET is initiated, else the oscilloscope is set according to the values found in the ram.
  It is this last routine that initiates AUTO SET after power up, if no backup batteries are installed.
- Finally the battery voltage is tested, and if it is too low, a message appears on the CRT screen.
  The battery check is only done in this stage of the power up routine; nowhere else during operation.
  The oscilloscope is now ready for operation.

Resumed:
- If the power up routine hangs up with both leds REP ONLY and NOT TRIG´D off, the microprocessor ram is defective.
- If it hangs up with only led NOT TRIG´D off, the display ram is defective.
- If stored traces or programmed front settings are cleared or an AUTO SET is initiated, while the backup batteries are OK, the contents of the microprocessor ram is destroyed. This may be caused by the oscilloscope being turned off at the moment the microprocessor was writing in the ram, but if it happens every time the oscilloscope is turned on the ram itself is broken.

NOTE: If the power up routine hangs up, the watchdog circuit on unit A6 is triggered regurlarly by the microprocessor, to prevent a new initiation of the power up routine again.

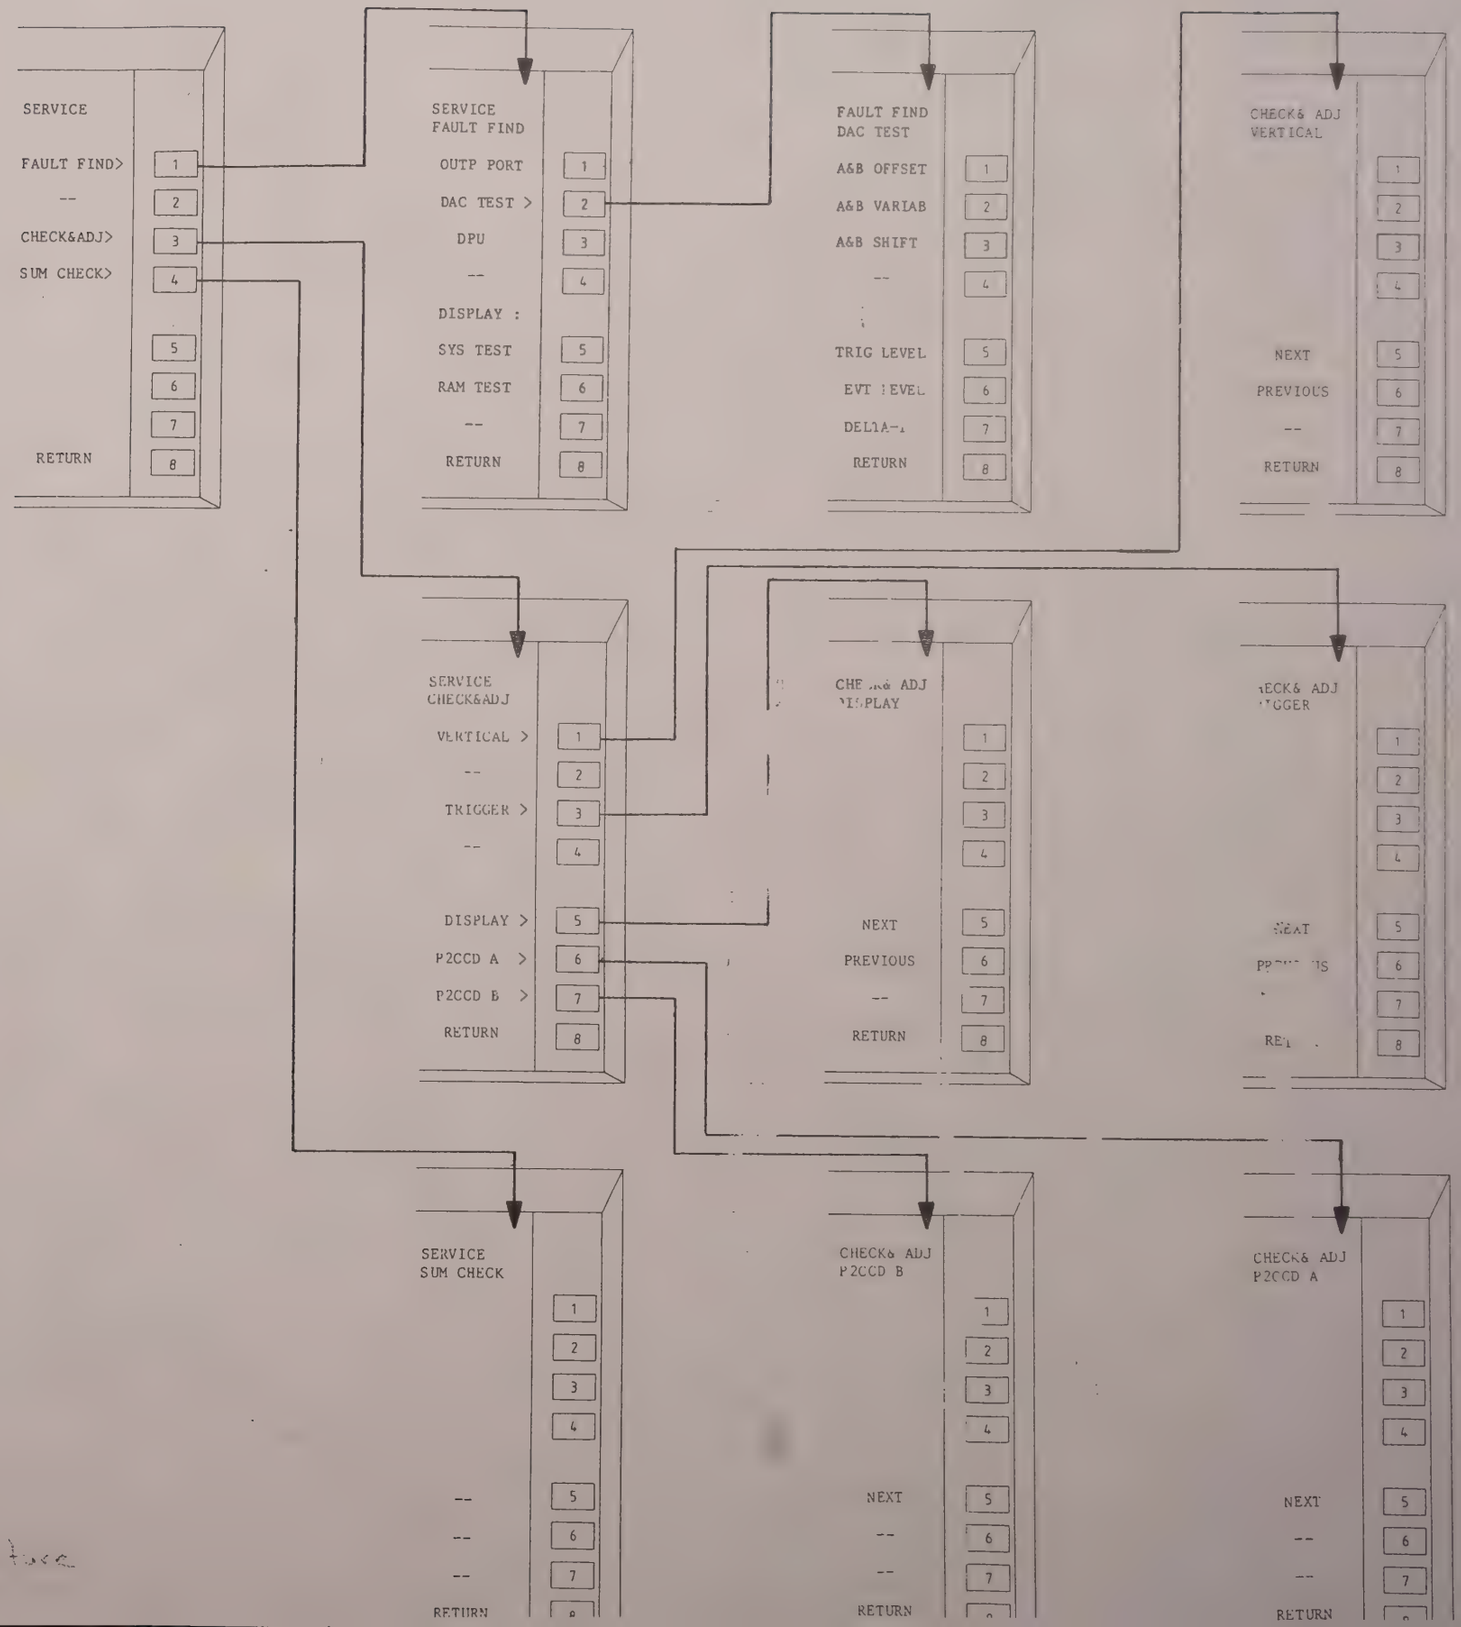

Figure 11.1 Service select menu structure

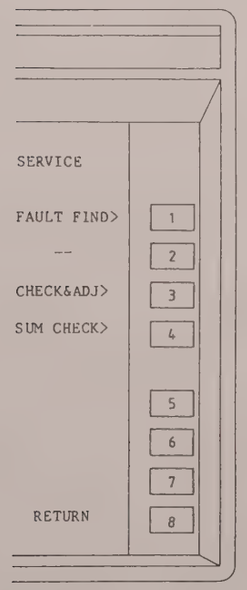
11.4.3 Softkey selectable diagnostic software

If some functions of the oscilloscope do not operate properly, the softkey selectable diagnostic software can be used to detect the defective hardware circuits.
This diagnostic software also contains a number of check and adjust routines (see chapter 9).

The routines destroy the actual front setting. Therefore returning to normal operation via the softkeys generates an AUTO SET.
It is always possible to return to normal operation by pressing the green pushbutton AUTO SET.
When a routine is operative and a setting is done on the front panel, the following message is given:

Instrument in SERVICE mode.
Changes are executed, but not always correct.

This is done because settings can not be executed if the concerning hardware is controlled by the selected diagnostic routine.



After pushing the upper and the lower softkey, the SERVICE menu appears on the screen. This menu allows selection of a range of fault find routines and a range of check & adjust routines (see figure 11.1)

Information about the software release is displayed at the left side of the softkeys 5 to 7.

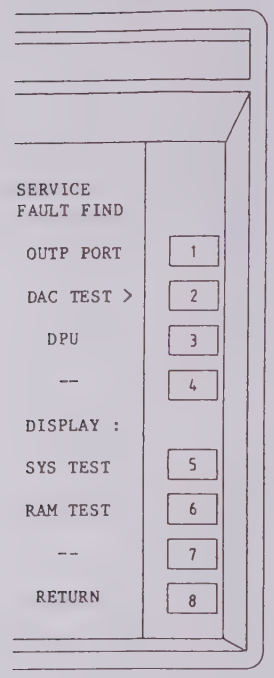
A message

For correct SERVICE handling:
*** switch off any active OPTION ***

may appear.

Options may be installed in the instrument, but they may not be active when the softkey selectable diagnostic software is used.
E.g. an interface should not display TIME and/or DATE.

1 FAULT FIND>



If FAULT FIND is selected the SERVICE FAULT FIND menu is displayed and a number of fault finding routines can be selected.

Each test can be stopped by pressing the same softkey again or by selecting another test.

In this part of the diagnostic software the traces are suppressed.

1 1 OUTP PORT

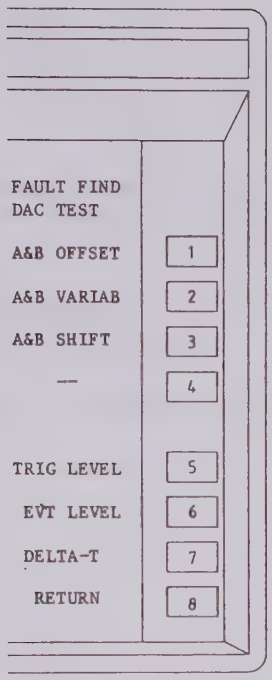
If OUTP PORT is selected an alternating pattern of zeroes and ones with a frequency of 1.6 Hz is generated at the following output ports on the management unit A25:

Name	IC nrs	Signal destination
delta-t control latch	D427	A34
attenuator control latch A	D409 + D411	A28 + A32
attenuator control latch B	D412 + D413	A29 + A32
vertical signal switch latch	D417	A33
trigger latches	D421 + D422	A31 + A32
P^2CCD output control latch	D436	A33

This test can be used to test the proper operation of these latches and their controlling hardware by checking all the outputs with an oscilloscope.

11

1 2 DACTEST>



If DACTEST is selected, the FAULT FIND DAC TEST menu is displayed.
With this menu all DAC´s in the acquisition section of the oscilloscope can be tested, by checking their output voltage with another oscilloscope.

Because the softkeys are only checked after a cycle of a test and the cycle can take some time (up to a few seconds), it may be necessary to keep a softkey pressed down a while to get the desired action.

1 2 1 A&B OFFSET

If A&B OFFSET is selected, a sawtooth signal is generated at the outputs of the OFFSET DACs of channel A and B (N403 and N404 on unit A25). During the slope of the sawtooth the digital values at the inputs of these 14 bit DACs is incremented by 16 every time. So the 4 less significant bits are not tested. The output voltage ranges from -5 to +5 V.
The period is 0,6 s.

Measuring points:

OSA: adaptation unit A35, X7451, pin 13
OSB: adaptation unit A35, X7451, pin 11

1 2 2 A&B VARIAB

If A&B VARIAB is selected, sawtooth signal is generated at the output of the SHIFT-VAR. DAC (N401 on unit A25). The output voltage is sampled and held by the Sample & Hold circuits VAR A and VAR B (N413 and N416 on unit A25).
During the slope of the sawtooth the digital value at the input of the 12 bit DAC is incremented by 4 every time. So the 2 less significant bits are not tested.
The output voltage of the DAC ranges from 0 V to -5 V.
The input and output voltages of the S&H circuits range from -5 V to +5 V.
The period is 2,5 s.

Measuring points:

DAC output voltage: N401 pin 18 on unit A25
S&H input voltages: N413 or N416 pin 3 on unit A25
VGA: vertical signal unit A32, X5206, pin 11.
VGB: vertical signal unit A32, X5206, pin 12

1 2 3 A&B SHIFT

If A&B SHIFT is selected, a sawtooth signal is generated at the output of the SHIFT-VAR. DAC (N401 on unit A25). The output voltage is sampled and held by the Sample & Hold circuits SHIFT A and SHIFT B (N412 and N414 on unit A25).
During the slope of the sawtooth the digital value at the input of the 12 bit DAC is incremented by 4 every time. So the 2 less significant bits are not tested.
The output voltage of the DAC ranges from 0 V to −5 V.
The input and output voltages of the S&H circuits range from −5 V to +5 V.
The period is 2,5 s.

Measuring points:

DAC output voltage: N401 pin 18 on unit A25
S&H input voltages: N412 or N414 pin 3 on unit A25
SHA: vertical signal unit A32, X5206, pin 15.
SHB: vertical signal unit A32, X5206, pin 9.

Note: SHA and SHB should be measured with the flatcable connector X5206 disconnected from A32. The signals can be measured on the flatcable part of the connector. If the connector is fitted, the voltages of SHA and SHB range from −6 V to +2 V.

1 2 4 --

1 2 5 TRIG LEVEL

If TRIG LEVEL is selected, a sawtooth signal is generated at the output of the TRIGGER LEVEL DAC (N407 on unit A25).
During the slope of the sawtooth the digital value at the input of this 14 bit DAC is incremented by 16 every time. So the 4 less significant bits are not tested.
The output voltage range from 0 V to +5 V.
The period is 0,5 s.

Measuring points:

TRDULV: vertical signal unit A32, X7014, pin 11.
TRLV : vertical signal unit A32, X7014, pin 23.

1 2 6 EVT LEVEL

If EVT LEVEL is selected, a sawtooth signal is generated at the output of the TRIGGER EVENT DAC (N406 on unit A25).
During the slope of the sawtooth the digital value at the input of this 14 bit DAC is incremented by 16 every time. So the 4 less significant bits are not tested.
The output voltage range from 0 V to +5 V.
The period is 1 s.

Measuring point:

TREVLV: external trigger unit A31, X4703, pin 2.

1 2 7 DELTA-T

If DELTA-T is selected, a sawtooth signal is generated at the output of the delta-t DAC (N8511 on clock unit A34).
During the slope of the sawtooth the digital value at the input of this 14 bit DAC is incremented by 16 every time. So the 4 less significant bits are not tested.
The output voltage range from 0 V to +11 V.
The top of the sawtooth is slightly clamped.
The period is 160 ms.

Measuring point:

Clock unit A34, IC N8512, pin 6.

1 2 8 RETURN

Return to SERVICE FAULT FIND menu.

1 3 DPU

If DPU is selected, the control memory of the DPU CONTROL unit A8 is loaded with a program that is run afterwards. This brings the DPU in a steady cycle, which enables testing of the system.
On a number of output signals of the DPU CONTROL a pulse is generated (see table below). These are all the output signals to the DPU (unit A9) and the trigger address comparator on unit A4, except TRRY and RSDU--LT.
The signals can be found on connector X1402.
The pulse width is 125 ns; the repetition time is 4,5 us.
All signals are at TTL level.

Signal name	Pinnr.	Signal name	Pinnr.
DUABØØ	C20	RDDURM	C26
DUABØ1	C21	SFSRØØ	C12
DUABØ2	A21	SFSRØ1	C11
DUABØ3	C22	STRLF	C15
DUABØ4	A22	ENOFD	A18
DUABØ5	C23	CKF	C25
DUABØ6	A23	CO	C13
DUABØ7	C24	SLAM	A28
DUABØ8	C16	RSDUR-LT	C19
DUABØ9	A17	OTDIAD	C29
DUAB1Ø	C18	OEDUØØ	A29
DUAB11	C17	OEDUØ1	A31
CSDURM	A27	LEDP	C31
CKDUR1	C3	SLOFAD	C27
CKDUR2-LT	A25	CNCPCN	A15
CKDUR3	A26	FBRY	C32

The state of the signals at the testpoints of unit A8 is:

Signal name	State
TRRY	Ø
EC	Ø
DAVA	Ø
ILØ2--LT	1
CKPL	Symmetrical square wave, cycle time = 125 ns.

1 4 --

1 5 DISPLAY SYS TEST

If DISPLAY SYS TEST is selected, the display system continuously displays the softkey text area, which can be seen as an intensified display. Traces, other text areas and miscellaneous text are not displayed. So the display system (units A1, A2, A3 and A4) is brought in a steady cycle, which enables testing of the system. See section 8.1 to 8.4 for the concerning hardware.

NOTE: if there is a failure in the display system, which causes the softkey text area not to be displayed, this test can not be selected in a visisble way. Nevertheless pushing the softkeys in the right sequence selects this test.

1 6 DISPLAY RAM TEST

If DISPLAY RAM TEST is selected, the display ram on unit A4 is tested. This ram consists of the text memory (D2014 and D2016) and the trace memory (D2008, D2009, D2011 and D2012). In the text memory the softkey text and the miscellaneous text is not tested.
If the test is completed succesfully, a message:

DISPLAY RAM test completed succesfully.

is displayed.
If the test fails, all leds on the front panel start blinking and the address where the failure is, is continuously read and written by the microprocessor.

NOTES: - this test destroys the contents of the trace memory, so after the test all traces are lost.
- as with the DISPLAY SYS TEST (see above), this test can be selected by pushing the softkeys in the right sequence, in case of a display failure.

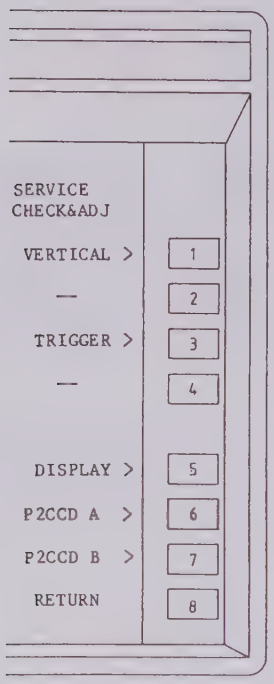
1 7 --

1 8 RETURN

Returns to SERVICE SELECT menu.

2 --

3 CHECK & ADJ>

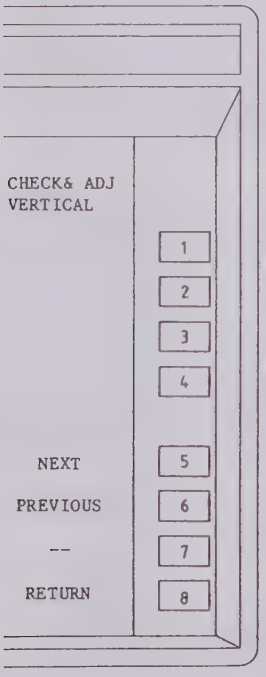


If CHECK & ADJ is selected, the CHECK & ADJ menu is displayed and a number of adjust routines can be selected.

Each routine is only operative if it is displayed.

See section 9.3 for detailed information about the use of the adjust routines.

3 1 VERTICAL>



If VERTICAL is selected, the CHECK & ADJ VERTICAL menu is displayed.
Information about the activated adjust routine for the vertical section of the oscilloscope is given at the left side of the softkeys 1 to 4.
The sequence number of the routine is displayed in the top of the menu behind "VERTICAL".

3 1 5 NEXT

Activates and displays the vertical adjust routine with the next higher sequence number.

3 1 6 PREVIOUS

Activates and displays the vertical adjust routine with the next lower sequence number.

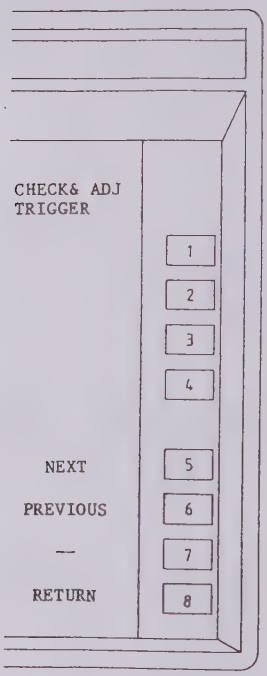
3 1 7 --

3 1 8 RETURN

Return to SERVICE CHECK & ADJ menu.

3 2 --

3 3 TRIGGER>



If TRIGGER is selected, the CHECK & ADJ TRIGGER menu is displayed.
Information about the activated adjust routine for the trigger section of the oscilloscope is given at the left side of the softkeys 1 to 4.
The sequence number of the routine is displayed in the top of the menu behind "TRIGGER".

3 3 5 NEXT

Activates and displays the trigger adjust routine with the next higher sequence number.

3 3 6 PREVIOUS

Activates and displays the trigger adjust routine with the next lower sequence number.

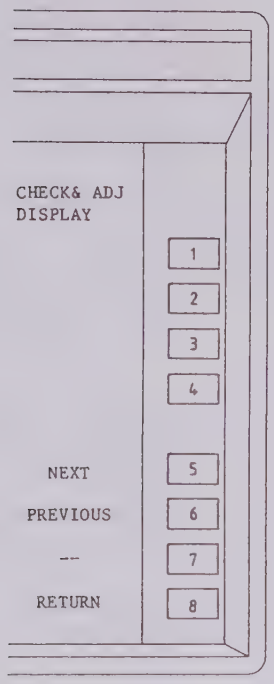
3 3 7 --

3 3 8 RETURN

Return to SERVICE CHECK & ADJ menu.

3 4 --

3 5 DISPLAY>



If DISPLAY is selected, the CHECK & ADJ DISPLAY menu is displayed.
Information about the activated adjust routine for the display section of the oscilloscope is given at the left side of the softkeys 1 to 4.
The sequence number of the routine is displayed in the top of the menu behind "DISPLAY".

Note:

When leaving the DISPLAY Ø menu it may be necessary to keep the key depressed for a short time, before any action takes place.

3 5 5 NEXT

Activates and displays the display adjust routine with the next higher sequence number.

3 5 6 PREVIOUS

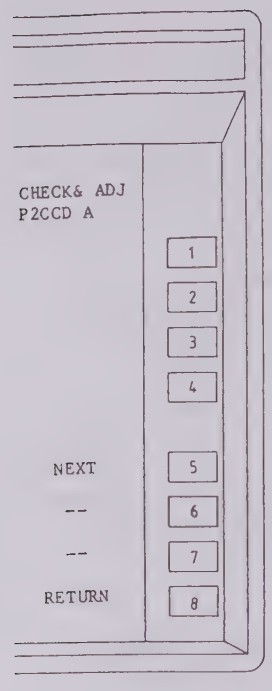
Activates and displays the display adjust routine with the next lower sequence number.

3 5 7 --

3 5 8 RETURN

Return to SERVICE CHECK & ADJ menu.

3 6 P2CCD A>



If P2CCD A is selected, the CHECK & ADJ P2CCD A menu is displayed.
Information about the activated adjust routine for the P^2CCD A section of the oscilloscope is given at the left side of the softkeys 1 to 4.
The sequence number of the routine is displayed in the top of the menu behind "P2CCD A".

3 6 5 NEXT

Activates and displays the P^2CCD A adjust routine with the next higher sequence number.

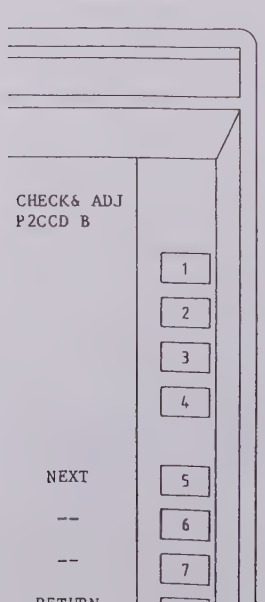
3 6 6 --

3 6 7 --

3 6 8 RETURN

Return to SERVICE CHECK & ADJ menu.

3 7 P2CCD B>



If P2CCD B is selected, the CHECK & ADJ P2CCD B menu is displayed.
Information about the activated adjust routine for the P^2CCD B section of the oscilloscope is given at the left side of the softkeys 1 to 4.
The sequence number of the routine is displayed in the top of the menu behind "P2CCD B".

3 7 5 NEXT

Activates and displays the P^2CCD B adjust routine with the next higher sequence number.

3 7 6 --

3 7 7 --

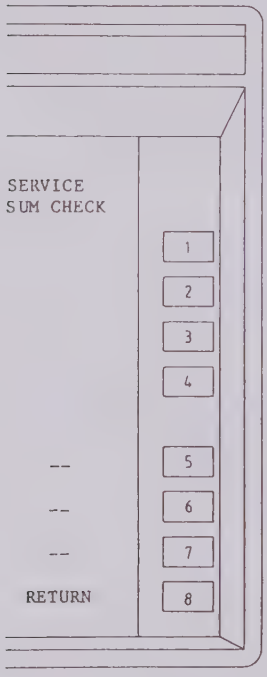
3 7 8 RETURN

Return to SERVICE CHECK & ADJ menu.

3 8 RETURN

Return to SERVICE CHECK & ADJ menu.

4 SUM CHECK>



If SUM CHECK is selected, the SUM CHECK menu is displayed.

At the left side of the softkeys 1 to 4 the sum check data are displayed.

4 5 --

4 6 --

4 7 --

4 8 RETURN

Return to SERVICE menu.

8 RETURN

Return to normal operation.
When a routine is still operative the following message is given:
Changes are executed, but not always correct.
This is done because settings can not be executed if the concerning hardware is controlled by the selected diagnostic.
Therefore this way of returning to normal operation is not recommended.

11.4.4 Hardware selectable diagnostic software

By changing over the service switches on unit A6, a number of service routines can be selected, which are suitable to test the hardware. For some routines not all hardware is needed. So these tests can be used by starting with the minimum required hardware and as long as the routines operate correctly more hardware can be connected until the routines do not operate anymore. The last connected hardware will be broken then.

The table below gives a survey of the tests.

Test	Service switches X1716	X1704	X1706	X1707	Minimum required hardware
Normal operation	fitted	down	down	down	all cards
RAM test	removed	down	up	down	A5 + A6
Front + output ports	removed	up	down	down	A5 + A6 + A8 + frontpanel
Address range	removed	up	up	up	A6

NOTES:
- Figure 11.2 shows the service switches in normal operation position.
- If X1716 is not fitted in normal operation, the oscilloscope may operate normally, but it is possible that it does not start up under certain conditions, because the watchdog circuit is disabled.
- Any options (A7 or A10) should be removed.

The RAM TEST enables testing of the microprocessor ram on unit A5. The test is a cyclic sequence that consists of the following parts:

- All leds on the frontpanel are turned on during 3 seconds.
- All leds are turned off, except the led ALIASED.
- The microprocessor ram is written with a certain pattern in a certain sequence.
- The led REP ONLY is turned on.
- The contents of the microprocessor ram is read back and checked. If the contents is OK, all leds are turned on during 3 seconds, etc. If the contents is wrong, the 3 leds ALIASED, REP ONLY and NOT TRIG´D start blinking with a frequency of about 2 Hz and the address where the failure is, is continuously read and written by the microprocessor.

The FRONTPANEL AND OUTPUT PORTS TEST enables the testing of the frontpanel and the output ports, which can not be tested by the softkey selectable output port test (see section 11.4.3).
When the test is started all leds on the frontpanel start blinking with a frequency of about 2 Hz.
After pushing a pushbutton, the softkeys included, or turning a rotary switch all leds are turned off.
Now the three leds ALIASED, REP ONLY and NOT TRIG´D form the display of a three byte binary counter. The counter counts the opening or closing of every pushbutton switch on the frontpanel as well as the level changes of the outputs of the rotary switches as they are turned. The counter counts always up, independent of the turning direction of the rotary switches.

01
ATTENTION MOS CIRCUIT
MAT 3261

While the front test is started by pushing a button or turning a rotary switch, the output port test is also started. This test writes an alternating pattern to hardware that is selected by signals with the following names:

Unit	Signal name	IC numbers
A2	WRVEPOLT	D2314 + D2316
A2	WRHOPOLT	D2317 + D2318 + D2332
A3	WRDPSTLT	D2119
A3	WRPSDPLT	D2103 + D2104
A3	WRDPPALT	D2106 + D2107
A3	WRHOVRLT	D2108
A5	--	D1807
A8	SLOT2	D1419
A8	SLOT4	D1421 + D1422

At the outputs of mentioned latches a symmetrical square wave appears with a repetition time of about 270 us.
Furtheron the alternating pattern is written to the following hardware:

Unit	Signal name	IC numbers
A3	Z + Interrupt timer	D2126
A5	Slow time base logic	D1801
A5	Acquisition control logic	D1802
A8	Control memory	D1426 + D1427 + D1428 + D1429

NOTE:
- This test can be done without unit A8 fitted, if a diode link is made between MYSLØ3LT (pin B6) and DATRAKLT (pin C8) on connector X1701. The anode of the diode should be connected to pin C8.

The ADDRESS RANGE TEST writes and reads in sequence the hexadecimal code 5555 to all addresses, followed by the same sequence with hexadecimal code AAAA.
The complete test takes about 74 seconds and is repeated automatically. Each address is read immediately after it is written. The read data are not checked.
During this test all levels of the lines of the microprocessor busses should change regularly.

NOTES:
- Data and address bus lines to other units via the motherboard (unit A12) only change if the address range outside unit A6 is addressed.
- This test can also be run with unit A6 removed from the oscilloscope and supplied by an external 5 Volt power supply.

11.5 RECALIBRATION AFTER REPAIR

After an electrical component has been renewed the calibration of that particular circuit should be checked, as well as the calibration of other closely related circuits.

Since the power supply affects all circuits, calibration of the entire instrument should be checked if work has been done in the power supply or if the transformer has been renewed.

12.0 HANDLING OF COMPONENTS AND SOLDERING TECHNIQUES

12.1 HANDLING OF COMPONENTS

12.1.1 Standard parts

Electrical and mechanical parts replacements can be obtained through your local PHILIPS organisation or representative. However, many of the standard electronic components can be obtained from other local suppliers. Before purchasing or ordering replacement parts, check chapter 15 "PARTS LISTS" for value, tolerance, rating and description.

NOTE: Physical size and shape of a component may affect instruments performance, particularly at high frequencies.
Always use direct replacement components, unless it is known that a substitute will not degrade the instruments performance.

12.1.2 Special parts

In addition to the standard electronic components, some special components are used:

- Components, manufactured or selected by PHILIPS to meet specific performance requirements.
- Components which are important for the safety of the instrument.

ATTENTION: Both type of components may only be replaced by components obtained through your local PHILIPS organisation or representative.

12.1.3 Transistors and integrated circuits

- Return transistors and I.C.'s to their original positions, if removed during routine maintenance.

- Do not renew or switch semi-conductor devices unnecessary, as it may affect the calibration of the instrument.

- Any replacement component should be of the original type or a direct replacement. Bend the leads to fit in the socket or pcb-holes and cut the leads to the same length as on the component being renewed.

- When a device has been renewed, check the operation of the part of the instrument, that may be affected.

- When re-installing power-supply transistors, use silicon grease to increase the heat-transfer capabilities.

WARNING: Handle silicon grease with care. Avoid contact with the eyes. Wash hands thoroughly after use.

12.1.4 Static sensitive components

This instrument contains electrical components (like for example the P^2CCD) that are suspectible to damage from static discharge. Servicing static-sensitive assemblies or components should be performed only at a static-free work station by qualified service personnel.

12.2 HANDLING OF MOS DEVICES

Though all our MOS integrated circuit incorporate protection against electrostatic discharges, they can nevertheless be damaged by accidental over-voltages. In storing and handling them, the following precautions are recommended.

CAUTION: Testing or handling and mounting call for special attention to personal safety. Personnel handling MOS devices should normally be connected to ground via a resistor.

12.2.1 Storage and transport

Store and transport the circuits in their original packing. Alternatively, use may be made of a conductive material or a special IC carrier that either short-circuits all leads or insulates them from external contact.

12.2.2 Testing or handling

Work on a conductive surface (e.g. metal table top) when testing the circuits or transferring them from one carrier to another. Electrically connect the person doing the testing or handling to the conductive surface, for example by a metal bracelet and a conductive cord to a chain. Connect all testing and handling equipment to the same surface. Signals should not be applied to the input while the device power supply is off. All unused input leads should be connected either to the supply voltage or to ground.

12.2.3 Mounting

Mount MOS integrated circuits on printed circuit boards after all other components have been mounted. Take care that the circuits themselves, metal parts of the board, mounting tools, and the person doing the mounting are kept at the same electric (ground) potential. If it is impossible to ground the printed-circuit board, the person mounting the circuit should touch the board before bringing the MOS circuits into contact with it.

12.2.4 Soldering

Soldering iron tips, including those of low voltage irons, or soldering baths should also be kept at the same potential as the MOS circuits and the board.

12.2.5 Static charges

Dress personnel in clothing of non-electrostatic material (no wool, silk or synthetic fibres). After the MOS circuits have been mounted, the proper handling precautions should still be observed.
Until the sub-assemblies are inserted into the complete system in which the proper voltages are supplied, the board is no more than an extension of the leads of the devices mounted on the board. To prevent static charges from being transmitted through the board wiring to the device it is recommended that conductive clips or conductive tape is put on the circuit board terminals.

12.2.6 Transient voltages

To prevent permanent damage due to transient voltages, do not insert or remove MOS devices, or printed circuit boards with MOS devices, from test sockets or systems with power on.

12.2.7 Voltage surges

Beware of voltage surges due to switching electrical equipment ON or OFF, relays and d.c. lines.

12.3 SOLDERING TECHNIQUES

Working method:

- Carefully unsolder one after the other the soldering tags of the semi-conductor.
- Remove all superfluous soldering material. Use a sucking iron or sucking litze wire.
- Check that the tags of the replacement part are clean and pre-tinned on the soldering places.
- Locate the replacement semi-conductor exactly on its place, and solder each tag to the relevant printed conductor on the circuit board.

NOTE: Bear in mind that the maximum permissible soldering time is 10 seconds during which the temperature of the tags must not exceed 250°C. The use of solder with a low melting point is therefore recommended.
Take care not to damage the plastic encapsulation of the semi-conductor (softening point of the plastic is 150°C).

ATTENTION: When you are soldering inside the instrument it is essential to use a low-voltage soldering iron, the tip of which must be earthed to the mass of the oscilloscope.

Suitable soldering irons are:

- ORYX micro-miniature soldering instrument, type 6 A, voltage 6 V, in combination with PLATO pin-point tip type 0-569.
- ERSA miniature soldering iron, type minor 040 B, voltage 6 V.
- Low voltage mini soldering iron, type 800/12 W-6 V, power 12 W, voltage 6 V, order no. 4822 395 10004, in combination with 1 mm pin-point tip, order no. 4822 395 10012.

Ordinary 60/40 solder with core and 35- to 40 W pencil type soldering iron can be used to accomplish the majority of the soldering. If a higher wattage-rating soldering iron is used on the etched circuit boards, excessive heat can cause the etched circuit wiring to separate from the board base material.

12.3.1. Soldering and desoldering of surface mounted devices

Introduction

This description gives you a method for replacing surface mounted devices (S.M.D.'s) and incorporates subjects such as:

- required tools and materials.
- how to arrange the S.M.D.-workshop. (see figure 12.1).
- general hints for S.M.D.-handling.
- interchanging S.M.D.'s with two or three connections.
- interchanging S.M.D.'s with four or more connections.

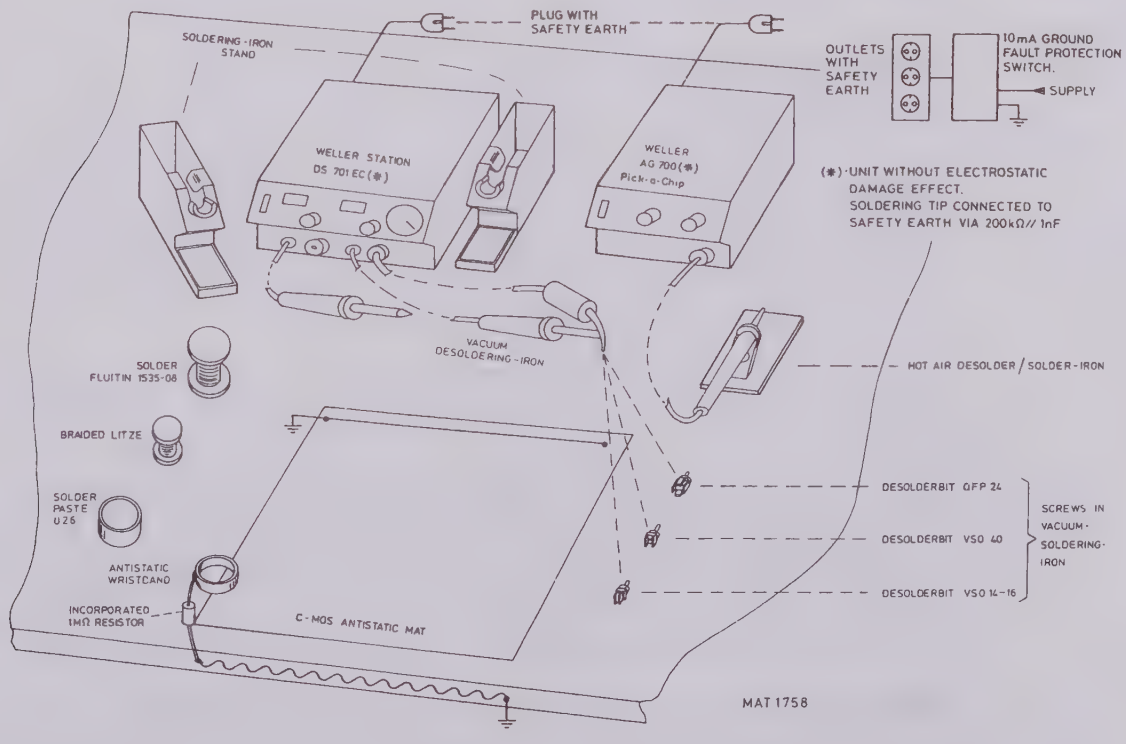

Figure 12.1 Arrangement of working area for S.M.D. exchange.

Required tools and materials

The following tools are necessary:

- A hot-air soldering/desoldering station for components with two or three leads: Weller AG 700 pick-a-chip.
- A vacuum, temperature controlled, soldering/desoldering station for components with four or more connections: Weller DS 701 EC.

- Desoldering accessories that can be attached to the Weller DS 701 EC-equipment: for dual-in-line S.M.D.'s VSO 14 and VSO 16 (with 14 and 16 connections such as used on the HF-attenuator p.c.b.) the types with Weller ordering code 587 13 701 and 587 13 702. For dual-in-line S.M.D.'s VSO 40 (with 40 connections such as used on the LCD-unit) the type with Weller ordering code 587 13 703. For QFP 24 S.M.D.'s (such as used on the time base chip unit) the type with Weller ordering code 587 13 704.
- A working area that has been secured against electro static discharge (E.S.D.).
- A pair of tweezers.

NOTE: The Weller equipment can be ordered via your local Weller-dealer.

The following material is necessary:

- "Fluittin" solder diameter of 0,8 mm, 15/35, Sn Pb 60.
- Solder paste 026.
- Components. Since not all the components are marked, they must be kept in their original packing in order to avoid interchanging them.
- Desoldering braided wire.

General hints for S.M.D.-mounting.

- Protection against E.S.D.: since the working area must be suitable for repair of MOS-devices, some precautions must be taken (see figure 12.1)
  All repairs must be done earthened which means that the repair surface, the soldering iron and the technician must be connected to the earth potential. This is achieved by using a C-MOS antistatic mat that must be connected to earth. The service-technician is connected to earth by wearing an antistatic wristband.
- Components: desoldered components cannot be used again since desoldering is done at a temperature of 350 degrees Celcius while they can only whitstand 240 degrees Celcius for max. 10 sec.
  Keep the new components as long as possible in their original packing in order to avoid damage and mixing up new and old S.M.D.'s.
- For an optimal supply of heat a working area must be used that does not lead away the heat: the antistatic mat in figure 12.1 meets this requirement.

Interchanging S.M.D.'s with two or three connections.

IMPORTANT: Before removing the component, observe very carefully its position in order to aviod that the new component is installed upside-down. This is especially important for capacitors where the metallisation at both ends is longer at the p.c.b. side than at the top side.

Use the equipment Weller AG 700 pick-a-chip and proceed as follows:

- Heat the component up equably with hot air of 350 degrees Celcius.
- Remove the component with a pair of tweezers.
- Clean the p.c.b. tracks, on which the new component has to be soldered, with braided wire or with the use of the vacuum desoldering equipment DS 701 EC.
- Put solder paste on the connections of the new component and position it on the p.c.b..
- Solder the component on to the p.c.b. with the solder described in the materials list. Soldering temperature must be 240 degrees Celsius, soldering time must not exceed 3 sec. per connection. The tip of your soldering iron must not touch the component, but must touch the p.c.b. track close to the component.

Interchanging S.M.D. s with four or more connections.

Use the equipment Weller DS 701 EC and attach a suitable desoldering piece (VSO 14, VSO 16, VSO 40 or OFP 24). Then proceed as follows:

- Adjust the desoldering temperature to 350 degrees Celcius and place the desoldering piece on the IC that has to be removed. Take care that all connections of the IC are equally heated up).
- Switch the vacuum on and lift the component from the p.c.b.
- Clean the p.c.b. tracks, on which the new component has to be soldered, with braided wire or with the use of the vacuum desoldering equipment DS 701 EC.
- Put solder paste on the connections of the new component and position it on the p.c.b.
- Position the component by soldering first the outside connections in a crosswise manner. Soldering temperature must be 240 degrees Celcius. Keep the soldering time as short as possible.
- Solder now the other connections.
- If necessary you must remove superfluous rests of solder with the use of braided wire.

13.0 SERVICE TOOLS

13.1 RECOMMENDED TEST AND CALIBRATION EQUIPMENT

Type of instrument	Specification	Used for	Example of required instruments
1. Constant amplitude sine-wave generator.	Freq. 50 kHz.. >300 MHz Voltage 10 mV.. 5 V	Bandwidth check of vertical channels and triggering	Tektronix SG503 + SG504
2. Time marker generator	Repetition rate 5 s ... 5 ns	Checking and adjusting of time base sweep rates including MAGN X10.	Tektronix TG501.
3. Square-wave calibration generator	Rise-time faster then 1 ns Voltage 10 mV up to (for prerefe-rence) 30 V Duty cycle 50%	Checking and adjusting of square-wave response of vertical channels and triggering	Generator with additional attenuators partly PG506.
4. LF sine-wave /sq.-wave generator	Sine-wave Freq.: 1 Hz... 1 MHz Voltage: 0... 30 V	Checking the LF trigger sensitivity	Philips PM5131
	Square-wave Freq.: 1 Hz... 1 MHz Voltage: 0... 30 V Rise time: faster then 100 ns	Checking and adjusting sq.-wave response of for instance attenuator unit	
5. Cables, T-piece, terminations and 10:1 attenuator	BNC-type		
6. Dummy probe 2:1	1 MOhm ±0,1%//14 pF	Check of input capacitance	

Type of instrument	Specification	Used for	Example of required instruments
7. Trimming tool kit	--	Adjustments	Philips SBC317 (ord. number 4822 310 50095)
8. Variable mains transformer.	Well-insulated Output voltage 90...264 VAC	Checking influence of mains voltage variations and adjustment of power supply.	Philips ord. number 2422 529 00005
9. Oscilloscope	The bandwidth must be the same or higher than the bandwidth of the instrument under test.	Checking and adjusting the instrument under test	Philips PM3295
10. Digital multimeter	Wide voltage, current and resistance ranges. Required accuracy 0,1%	Checking and adjusting the instrument under test	Philips PM2718
11. BNC probe tip adapter	--	Checking bandwidth of the oscilloscope via probe.	Philips 5322 263 50022
12. BNC banana adapter	--	Checking the variable gain balance.	Philips PM 9051
13. Stabilized power supply	0-12 V d.c./ 1 mA	Checking the penlift signal of the plot output.	Philips PE 1535
14. Plot out cable DIN/ 6x banana	--	Checking and adjusting of the plot output.	Philips 5322 321 20908
15. Constant sine-wave generator	245...1050 MHz	Checking the trigger sensitivity at 300 MHz.	Tektronix SG 504

13.2 DUMMY LOAD FOR POWER SUPPLY (unit A20)

Information for an easy access to the power supply and for safe working conditions can be found in chapter 10 "DISASSEMBLING AND ASSEMBLING". This chapter also explains how to measure the power supplies in working condition.
The position of the rear side panel of the oscilloscope under test is also indicated in chapter 10.

In order to be able to determine whether a certain fault condition is initiated by the power supply itself or by the connected oscilloscope circuits, a dummy load is listed in the table below. The table gives also an example of the resistor types that can be used to compose the dummy load: the resistors can be ordered at Concern Service.

The dummy load resistors must be mounted on a p.c.b. and connected via a (flat)cable to X4604 on unit A20 (mounted on rear side panel).
The connector pins are also given in the diagram of chapter 8.20.
Electrolytic capacitors in the dummy load are not necessary because of the capacitive values present on the power supply unit itself.

Supply Voltage	Connector pin(s) X4604 (A20)	Output Current	Power dissi-pation	Dummy load
+5 V (+5 D)	30A-30C-31A-31C-32A-32C	5 A	25W	10 resistors of 10 Ohm, 4 W in parallel: 4822 112 21054
-5 V (-5 D)	13A-13C-14A-14C-15A-15C	2,2 A	11 W	4 resistors of 10 Ohm, 4 W: 4822 112 21054 and 1 resistor of 39 Ohm, 4 W: 4822 112 21069 in parallel
+7 V	16A-16C	550 mA	3,9 W	2 resistors of 27 Ohm, 4 W: 4822 112 21065 in parallel
-7 V	17A-17C	1,2A	8,4 W	2 resistors of 12 Ohm, 7 W: 4822 112 41056 in parallel
+14 V	20A-20C-21A-21C	1,2A	16,8 W	2 resistors of 27 Ohm, 11 W: 4822 112 31065 and 1 resistor of 100 Ohm 4 W: 4822 112 21081 in parallel
-14 V	18A-18C-19A-19C	1A	14 W	2 resistors of 8,2 Ohm, 4 W: 4822 112 21052 in parallel, with 1 resistor of 10 Ohm 11 W: 4822 112 31054 in series
+19 V	23A-23C	150 mA	2,9 W	1 resistor of 100 Ohm, 4 W: 4822 112 21081 in series with 27 Ohm , 4 W: 4822 112 21065
-19 V	22A-22C	250 mA	4,8 W	2 resistors of 150 Ohm, 4 W: 4822 112 21085 in parallel
+40 V	24A-24C	120 mA	4,8 W	1 resistor of 330 Ohm, 7 W: 4822 112 41094
+100 V	12 A	20 mA	2 W	1 resistor of 4,7 kOhm, 4 W: 4822 112 21125
ϟ 6,3 V a.c filament C.R.T.	X4602 pins 3 and 1	250 mA	1,6 W	lamp 6,3 V 250 mA: 4822 134 40007

13.3 SPECIAL TOOLS

13.3.1 Special tool for the slotted nuts on the front panel.

A special tool is available for the slotted nuts on the front panel, code number 5322 395 54024.
For those who want to make such a tool, a sketch is given below with the dimensions in mm.
The material is silversteel NO94, tempered 40-45RC.

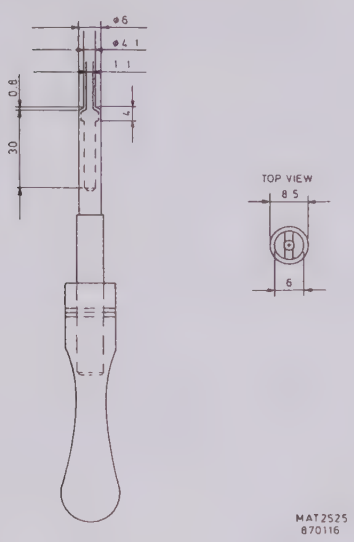

Figure 13.1 Dimensional drawing of tool for slotted nut.

13.3.2 Special tool for removing the S.M.D. modules from the p.c.b.´s

To remove the S.M.D. modules from the vertical signal unit A32, CCD logic A26 and from the clock unit A34, a special cutnipper must be used for instance:

Lindström - Eskilstuna - Sweden type 3511 or
Erem - Geneve - type 504AE/110 (oblique cutnipper).
Service ordering number: 5322 395 90564

13.3.3 Extension board for the units A1 ... A11 and A20

For test and repair purposes the unit A1 ... A11 or A20 can be plugged in their connectors via an extension board available under codenumber 5322 216 51153
The position of the rear side panel with unit A20 connected to the management unit A25 via the above mentioned extension card is indicated in chapter 10.

13.3.4 Special tool for removing integrated circuits (DIL package)

For cutting the connection pins of integrated circuits a special cutnipper is available under ordering number 5322 395 71004

14.0 SAFETY INSPECTION AND TESTS AFTER REPAIR AND MAINTENANCE IN THE PRIMARY CIRCUIT

14.1 SAFETY INSPECTION AND TESTS

14.1.1 General directives

- Take care that the creepage distances and clearances have not been reduced.
- Before soldering, the wires should be bent through the holes of solder tags, or wrapped around the tag in the form of an open U, or, wiring ridigity shall be maintained by cable clamps or cable lacing.
- Replace all insulating guards and -plates.

14.1.2 Safety components

Components in the primary circuit may only be renewed by components selected by PHILIPS, see also clause 12.1.2.

14.1.3 Checking the protective earth connection

The correct connection and condition is checked by visual control and by measuring the resistance between the protective lead connection at the plug and the cabinet/frame. The resistance shall not be more than 0,1 Ohm. During measurement the mains cable should be removed from the mains. Resistance variations indicate a defect.

14.1.4 Checking the insulation resistance

Measure the insulation resistance at U = 500V dc between the mains connections and the protective lead connections. For this purpose set the mains switch to ON. The insulation resistance shall not be less than 2 MOhm.

NOTE: 2 MOhm is a minimum requirement at 40°C and 95% Relative Humidity. Under normal conditions the insulation resistance should be much higher (10 ... 20 MOhm).

14.1.5 Checking the leakage current

The leakage current shall be measured between each pole of the mains supply in turn, and all accessible conductive parts connected together (including the measuring earth terminal).
The leakage current is not excessive if the measured currents from the mentioned parts does not exceed 0,5 mA rms.

14.1.6 Voltage test

The instrument shall withstand, without electrical breakdown, the application of a test voltage between the supply circuit and accessible conductive parts that are likely to become energized. The test potential shall be 1500 V rms at supply-circuit frequency, applied for one second.
The test shall be conducted when the instrument is fully assembled, and with the primary switch in the ON position.
During the test, both sides of the primary circuit of the instrument are connected together and to one terminal of the voltage test equipment; the other voltage test equipment terminal is to be connected to the accessible conductive parts.

14.2 INSTRUMENT REPACKING

If the instrument is to be shipped to a Service Centre for service or repair, attach a tag showing the full addres and the name of the individual at the users firm that can be contacted. The Service Centre needs the complete instrument, its serial number and a fault description. If the original packing is not available, repack the instrument in such a way that no damage occurs during transport.

15.0 PARTS LISTS

SUBJECT TO ALTERATION WITHOUT NOTICE

In this chapter the mechanical and electrical parts are listed.

The item numbers of the parts are indicated in the figures of this chapter.

The opening of parts, or removal of covers, is likely to expose live conductors. The instrument should therefore be disconnected from all voltage sources before any opening of parts or removal of covers is started.
During and after dismantling, bear in mind that capacitors in the instrument may still be charged even if the instrument has been separated from all voltage sources.

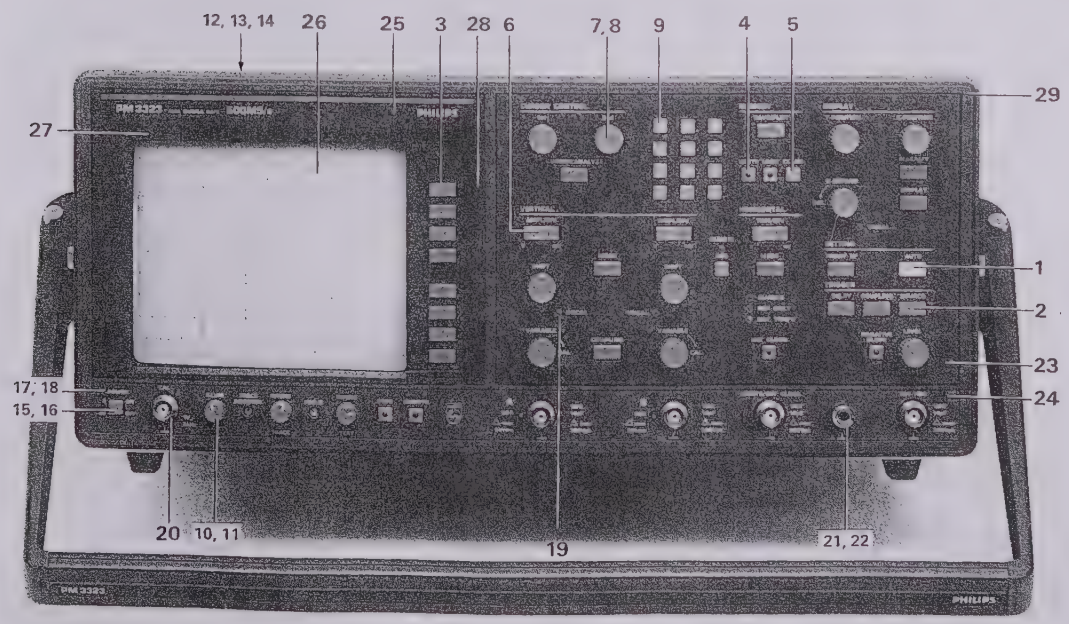
15.1 MECHANICAL PARTS

15.1.1 Mechanical + electrical parts front side (figure 15.1)

Item	Qty/. instr.	Description	Ordering number
1	1	Green pushbutton cover for: S4229 AUTO SET	5322 414 20186
2	11	Brown pushbutton cover (12,5 x 6,5) for: S4224 CURSOR/ANALYZE S4221 VERTICAL MODE S4219 VERTICAL COUPLING S4217 SAVE/PLOT S4222 HORIZONTAL MODE S4216 MAGNIFY S4218 DISPLAY S4226 FRONT NO S4228 TRIGGER DELAY S4223 TRIGGER COUPLING S4227 TRIGGER SOURCE	5322 414 60037
3	8	Brown pushbutton cover (12,5 x 6,5) for: S4 SOFTKEY 1 S5 SOFTKEY 2 S6 SOFTKEY 3 S7 SOFTKEY 4 S8 SOFTKEY 5 S9 SOFTKEY 6 S10 SOFTKEY 7 S11 SOFTKEY 8	5322 414 20185

Item	Qty/. instr.	Description	Ordering number
4	4	Brown pushbutton cover assembly (6,5 x 6,5) with led window for: S4233 WRITE S4234 LOCK S4231 EXT CLOCK S4237 NEG SLOPE S2 DOTS S3 SMOOTH	5322 414 60038
5	2	Brown pushbutton cover and switch (6,5 x 6,5) for: S4236 CLEAR S4232 URQ	5322 276 11856
6	3	Brown UP/DOWN-control cover (18 x 6,5) and switch for: S4238 A AMP/DIV S4239 B AMP/DIV S4241 TIME/DIV	5322 277 10878
7	10	Brown knob dia 14 mm for rotary controls: CURSOR 1st CURSOR 2nd SHIFT A SHIFT B VARIABLE A VARIABLE B Y-POSITION X-POSITION X-EXPAND LEVEL	5322 414 30062
8	10	Brown cover for 14 mm knob for rotary controls:	5322 414 70015
9	1	Key unit (12 keys with numbered covers)	5322 218 41032
10	3	Brown knob dia 10 mm for: R1 ILLUM R3 INTENS TRACE R5 INTENS TEXT	5322 414 30044
11	3	Brown cover with white marking line: R1 - R3 and R5	5322 414 70016
12	2	Illumination lamp E1 and E2 (28 V - 80 mA)	5322 134 40534
13	1	Illumination lampholder	5322 255 24015
14	1	Light cover for illumination lampholders	5322 380 10021
15	1	POWER ON knob	5322 414 60142
16	1	Spring for POWER ON knob	5322 492 41354
17	1	POWER ON ledholder	5322 255 40231
18	1	POWER ON led CQW54-VI H1	5322 130 32704

19	7	Led TLHR 4613 for: UNCAL A H4204 UNCAL B H4206 REMOTE H4207 ALIASED H4201 REP ONLY H4202 NOT TRIG´D H4203 UNCAL X-EXPAND H4208	4822 130 31128
20	5	BNC socket for: X1 CAL X2 A X3 B X4 EVENTS/EXT CLOCK X6 EXT TRIG	5322 267 10191
21	1	Knurled nut for earth connector X5	5322 505 14178
22	1	Thread end for earth connector X5	5322 535 84446
23	1	Front text plate (with adhesive backside)	5322 455 11009
24	1	Textplate under C.R.T. (with adhesive backside)	5322 455 11008
25	1	Textstrip above C.R.T. (with adhesive backside)	5322 455 81087
26	1	Blue contrast filter	5322 381 10963
27	1	Bezel (window for contrast filter)	5322 450 60977
28	2	Spring for bezel	5322 492 70273
29	1	Plastic front frame	5322 447 91377
-	1	Front cover (without inner plate)	5322 447 91378
-	1	Inner plate of front cover	5322 447 91376



15.1.2 Mechanical + electrical parts rear side (figure 15.2 and 15.3)

Item	Qty/. instr.	Description	Ordering number
1	4	Distance piece for rear foot	5322 462 50385
2	2	Rear foot (without rubber feet)	5322 462 41135
3	4	Rubber foot for rear foot	5322 462 40765
4	4	Screw for rear foot	5322 502 12882
5	4	Distance peace for rear foot	5322 532 24591
6	4	Washer	5322 532 14593
7	4	Spring washer	4822 530 80163
8	1	Cover for battery holder	5322 462 40766
9	2	Battery holder	5322 256 64014
10	1	Rear plate	5322 447 91698
11	1	PLOT output socket X17	4822 267 40039
12	1	Power inlet X19 (Fuse holder + mains input socket)	5322 219 81131
13	1	Fuse 2,5 A TZ F1	4822 253 30026
14	1	Fan M1	5322 361 10453
15	1	Fan protection grid	5322 466 30269
16	2	Rear profile (without strip and grounding spiral)	5322 466 61845
17	70cm	HF grounding spiral for rear profile	5322 492 70274

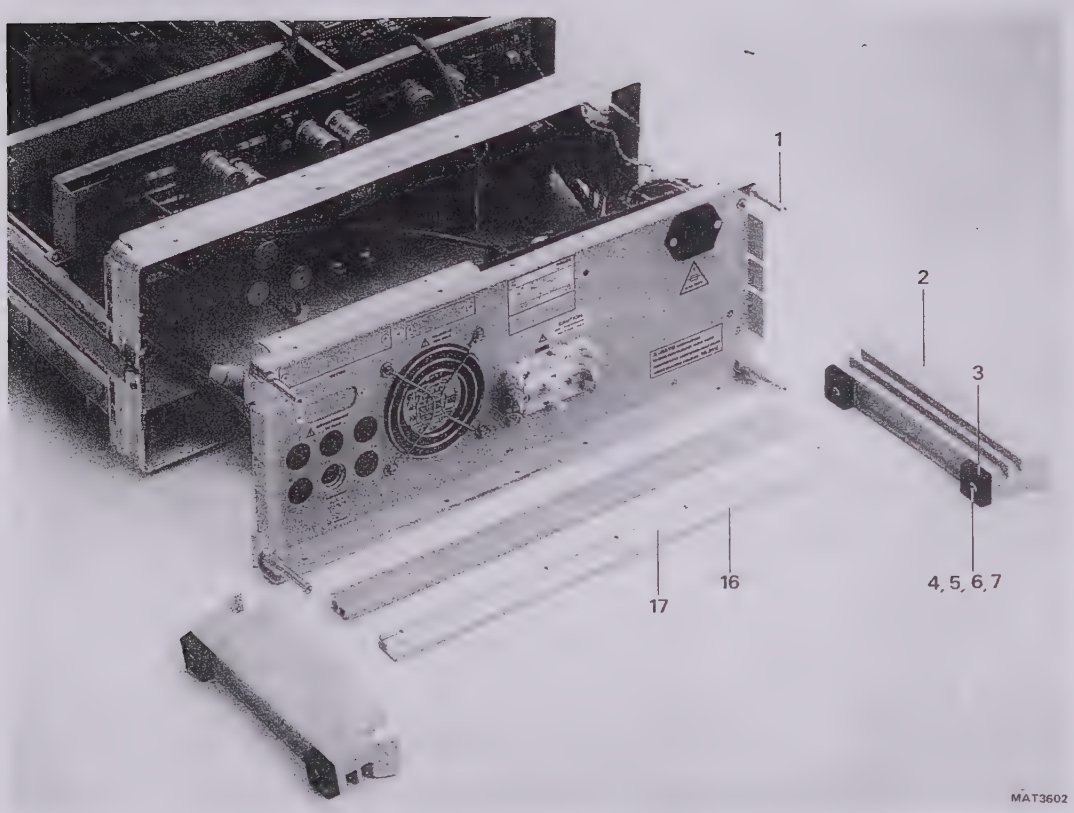


Figure 15.2 Mechanical parts rear side.

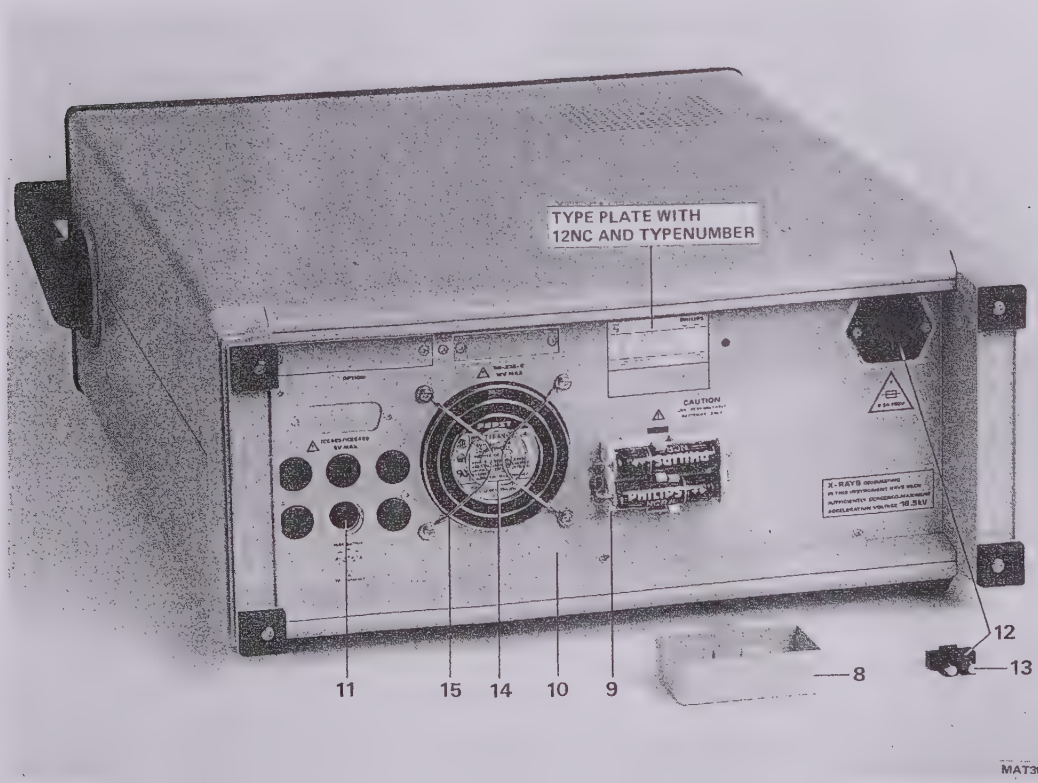

15.1.3 Carrying handle and housing (figure 15.4 and 15.5)

Carrying handle

Item	Qty/. instr.	Description	Ordering number
1	2	Locking pin	5322 535 74401
2	2	Spring	5322 492 54155
3	1	Handle arm left	5322 498 50225
4	1	Handle arm right	5322 498 50226
5	1	Metal carrying profile	5322 466 61554
6	1	Plastic carrying profile cover	5322 466 61555
7	1	Textstrip	5322 455 81088
8	4	Screw	4822 502 10064

Housing

Item	Qty/. instr.	Description	Ordering number
9	2	Beige side profile (left or right)	5322 466 61553
10	2	Beige handle ring	5322 498 50242
11	1	Top cover	5322 447 91697
12	4	Cap for pouch holes	5322 462 71476
13	1	Bottom cover	5322 447 91375
14	4	Foot (bottom side)	5322 462 50325

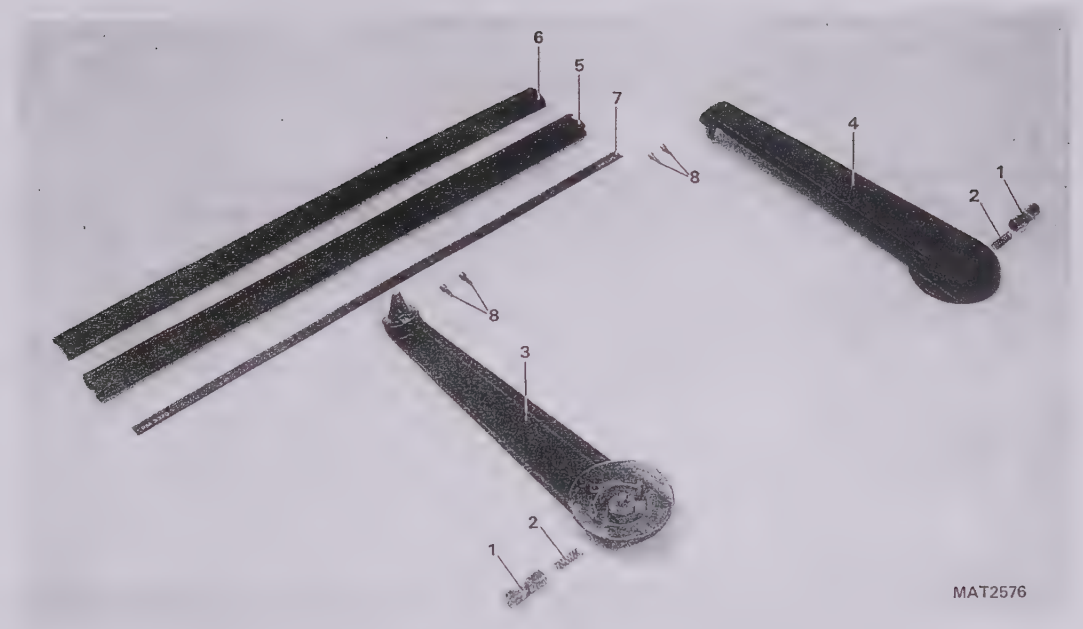

Figure 15.4 Carrying handle.

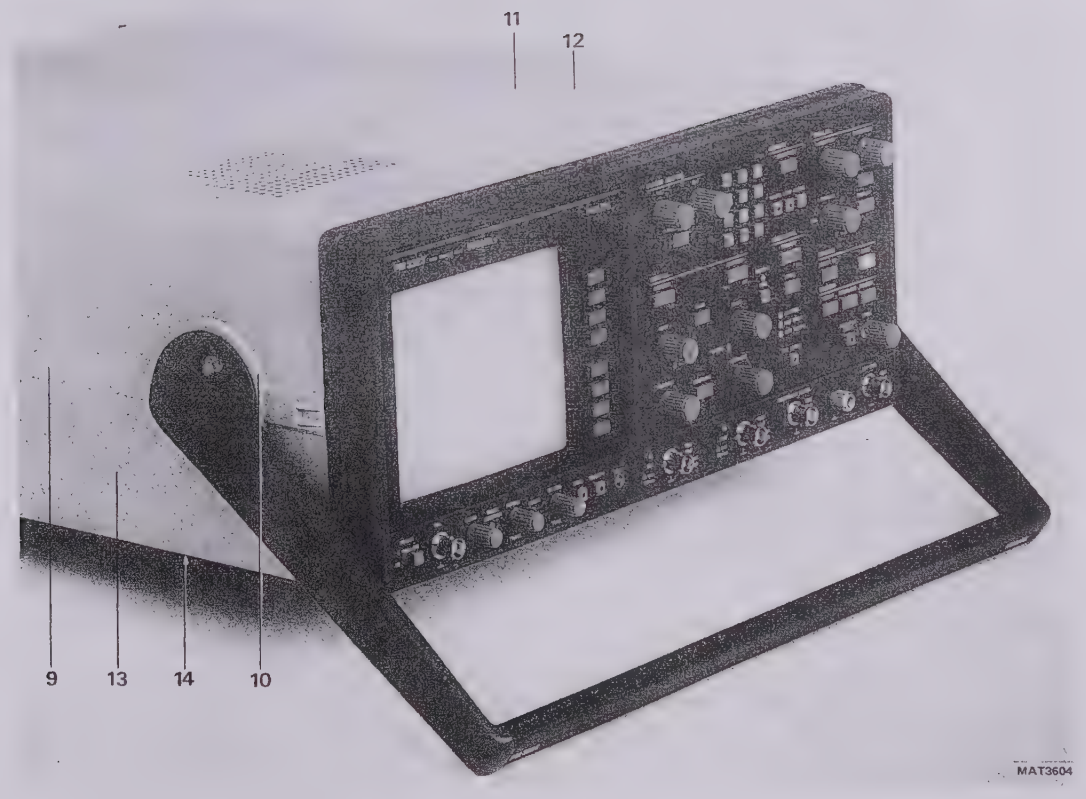

Figure 15.5 Housing.

15.1.4 Internal mechanical parts for front unit (figure 15.6)

Item	Qty/. instr.	Description	Ordering number
1	10	Prism for rotary shaft encoder	5322 256 91198
2	10	Lock for rotary shaft encoder	5322 532 51869
3	10	Rotary shaft encoder	5322 535 91823
4	10	Fixture for leds and fototransistors	5322 256 91199
5	5	Slotted nut for textplate	5322 505 14186
6	4	Spacer	5322 535 92926
7	6	Distance piece M3 x 20	5322 535 91905

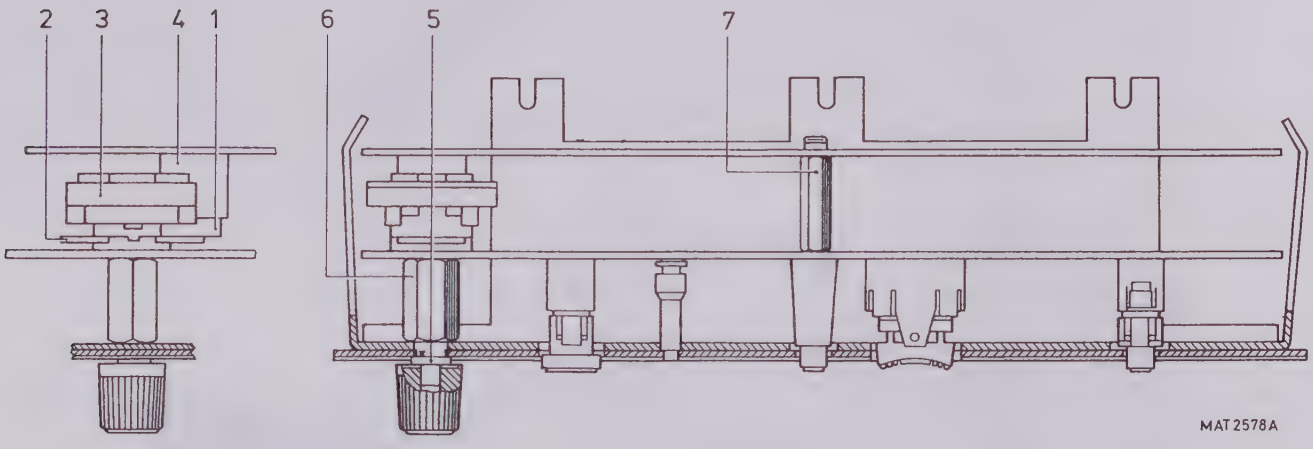

Figure 15.6 Mechanical parts front unit.

15.1.5 C.R.T. fixing materials (figure 15.7)

Item	Qty/. instr.	Description	Ordering number
1	1	C.R.T. socket X1504	5322 255 40502
2	1	Earthing spring for C.R.T. shielding	5322 492 63718
3	6	Gummi parts in C.R.T. shielding	5322 466 61556
4	1	Plastic/rubber pressure support for C.R.T.	5322 462 41136
5	3	Gummi parts around C.R.T. front	5322 532 11588
6	1	Plastic clamping fork for front side of C.R.T.	5322 401 11112
7	1	Metal wedge for front side of C.R.T.	5322 535 20072
8	1	Metal clamping piece for front side of C.R.T.	5322 535 20071

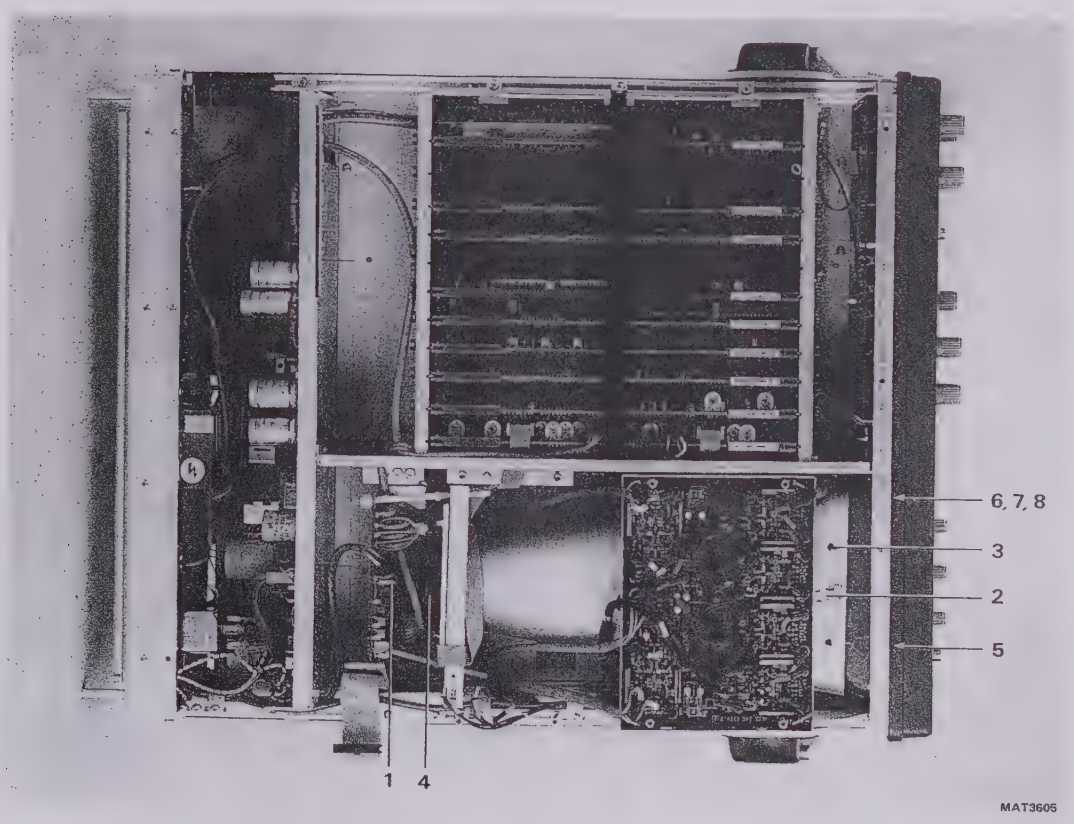

Figure 15.7 C.R.T. fixing materials.

15.1.6 Miscellaneous parts (figure 15.8)

Item	Qty/. instr.	Description	Ordering number
1	1	C.R.T. D18-190GH/129 V1	5322 131 20205
2	22	Plastic conductor for units A1..A11	5322 401 11109
3	18	Red p.c.b. handle	5322 401 11108
4	18	Pin for red p.c.b. handle	5322 402 10036
5	1	Bracket over plug-in units	5322 401 11113
6	3	Ball cord for unit A15	5322 401 11114
7	5	Spring for heatsink on unit A19 for transistors: V4447 - V4448 - V4429 - V4424 - V4426	5322 492 63721
8	1	Bracket for high voltage unit D4601	5322 401 11111
9	1	Power on switch S1	5322 276 11859
-	110	Coding pin for DIN connectors	5322 268 10254

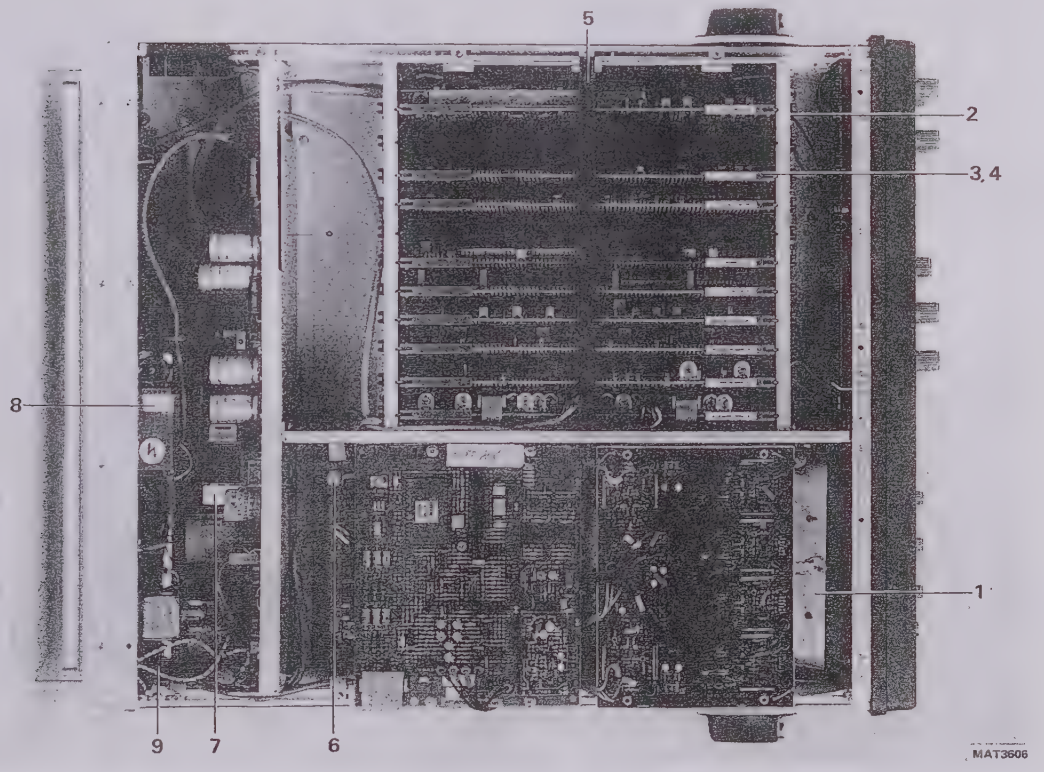

Figure 15.8 Miscellaneous parts.

15.2 ELECTRICAL UNITS (Figures 15.9 and 15.10)

Item	Description	Ordering number
A1	Final amplifier unit	5322 216 51154
A2	Display dac unit	5322 216 51155
A3	Display control unit	5322 216 51156
A4	Display memory unit	5322 216 51157
A5	MRAM unit	5322 214 90188
A6	UPROC unit	5322 214 90187
A8	DPU control unit	5322 216 51161
A9	DPU unit	5322 216 51162
A11	ADC + T&H unit	5322 216 51163
A13	FRONT 1 unit	5322 216 51176
A14	FRONT 2 unit	5322 216 51178
A15	Z-amplifier unit	5322 216 51164
A16	C.R.T. control unit (inclusive unit A18 SMOOTH + DOTS unit)	5322 216 51179
A17	Softkey unit	5322 218 41031
A19	POWER 1 unit	5322 216 51182
A20	POWER 2 unit	5322 216 51183
A24	DRIVER unit	5322 216 51234
A26	CCD logic unit	5322 216 51235
A27	HF attenuator unit	5322 216 51081
A28	LF attenuator unit	5322 216 51184
A29	HF attenuator unit	5322 216 51081
A30	LF attenuator unit	5322 216 51184
A31	External trigger unit	5322 216 51185
A33	P^2CCD unit	5322 216 51236
A34	Clock unit	5322 216 51237
A38	Mini trigger select unit	5322 216 51166
A39	Mini trigger select unit	5322 216 51166
A40	Mini trigger filter unit	5322 216 51167
A41	Mini trigger amplifier unit	5322 216 51168
A42	Mini trigger logic unit	5322 216 51169
A43	Mini events/amplifier unit	5322 216 51171
A44	Mini vertical amplifier proc.	5322 216 51172
A48	Mini frequency doubler	5322 216 51238
A49	Mini CCD logic unit	5322 216 51175
A51	Attenuator relais unit	5322 216 51187
A65	Attenuator unit complete	5322 693 11073
-	Extension board	5322 216 51153
-	EHT unit	5322 216 51177
-	Set of software	5322 310 10309

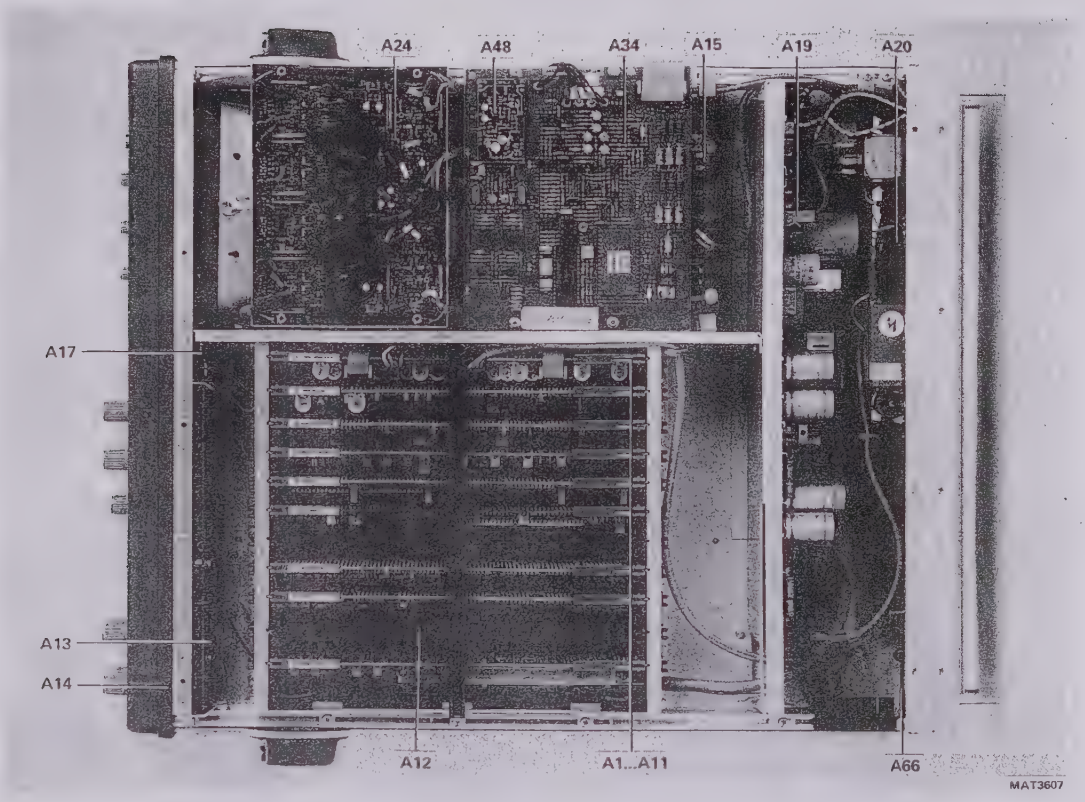

Figure 15.9 Position of electrical units.

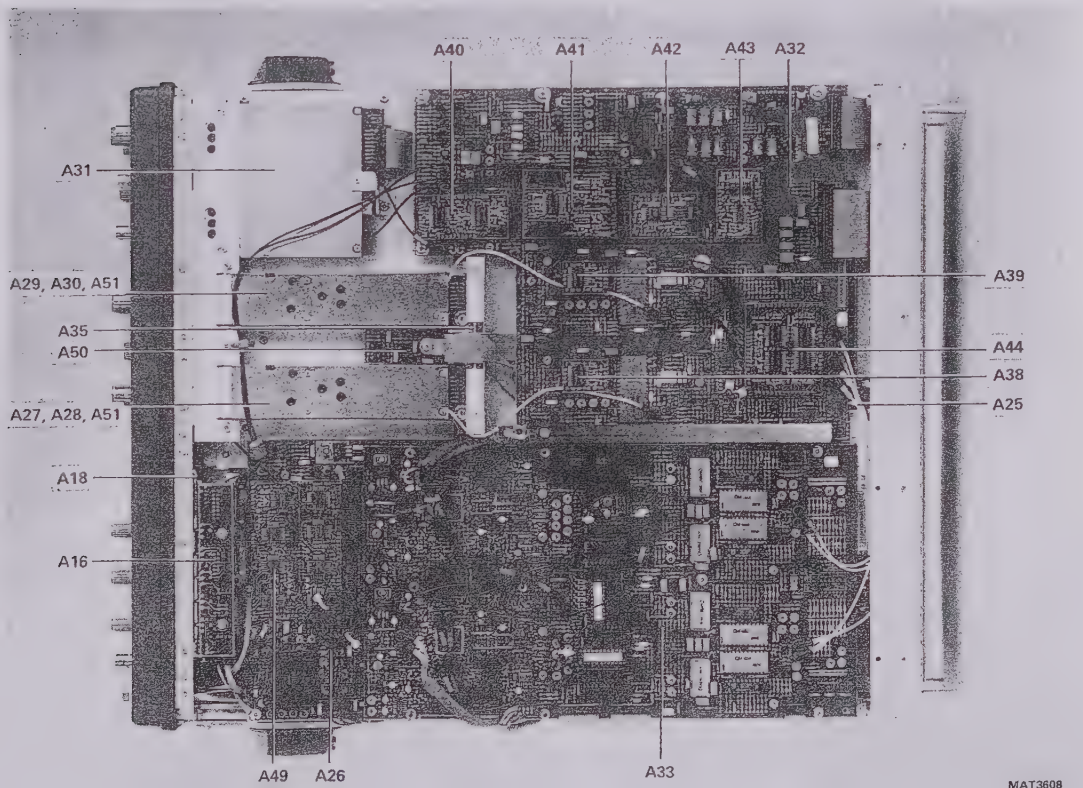

15.3 CABLES AND CONNECTORS

15.3.1 Flatcables and connectors

The following flatcables are available:	Ordering number
50 Pole flatcable from X4403 on unit A19 to X4606 on unit A20	5322 321 23424
64 Pole flatcable from X501 on unit A12 to X2502 on unit A25	5322 321 23427

The remaining flatcables used in this oscilloscope must be made by yourself with the following parts:

- Universal flatcable, 40 wires, length 60 cm	5322 323 50112

To get the required number of wires the flat cable must be split by means of a pair of scissors or a knife.
The cable must be cut on the required length.

- Flatcable connectors

The connectors can be mounted on the flatcable by means of a pair of pliers or in a bench-vice.

Attention: check the position of the flatcable in the connector before pressing the connector together.

The following connectors are available:	Ordering number
10 pole cable connector	5322 265 51117
20 pole cable connector	5322 265 54059
24 pole cable connector	5322 265 51114
26 pole cable connector	5322 267 60164
34 pole cable connector	5322 267 70163
40 pole cable connector	5322 267 70162
Nylon clamps to lock connectors (36 per instr.)	5322 401 11156

15.3.2 Coax cables

The following coax cable sets are available:	Ordering number
Cable set 75 ohm (2 cables per set) between unit A24 and A33	5322 321 23429
Cable set 50 ohm (4 cables per set) between unit A24 and A33	5322 321 23428

The remaining 50 ohm coax cables are standardized, so some cables are a little bit too long. The tules around the cable ends can have a different colour, but if necessary it can be replaced by the original one.

Cable length	Ordering number
20 cm	5322 321 21291
26 cm	5322 321 21293
31 cm	5322 321 21292

15.3.3 Miscellaneous cables and connectors	Ordering number
High voltage cable from X4602 on unit A20 to X1503 on unit A15	5322 321 23426
High current cable from X4404 on unit A19 to X528 on unit A12	5322 321 23425
Connector (5 pole) for X4401 on unit A19	5322 267 50452
Kontakt bush	5322 268 24128
Connector (3 pole) for X3001 on unit A16	5322 268 40233
Kontakt bush	5322 268 20165
Connector (3 pole) for X4402 on unit A19 X4601 on unit A20 X4603 on unit A20 X3304 on unit A33	5322 268 40233
Kontakt bush	5322 268 20165
Connector (4 pole) for X3002 on unit A16 for X1502 on unit A15	5322 268 40269
Connector (5 pole) for X104 on unit A1	5322 268 40279
Kontakt bush	5322 268 20152
Connector (4 pole) for X103 on unit A1	5322 268 40269
Kontakt bush	5322 268 20176

15.3.4 Coax connector socket (70 connectors per instrument)	
Outer part (bush)	5322 268 24116
Inner part (pin)	5322 268 14141

15.4 MAINS CORDS:

	Last digit 12nc of oscilloscope (on packing)	
European version	1	5322 321 21616
U.S.A. version	3	5322 321 10446
U.K. version	4	5322 321 21617
Swiss version	5	5322 321 21618
Australian version	8	5322 321 21781

15.5 TOOLS:

Oblique cutnipper	5322 395 90564
Cutnipper	5322 395 71004
Extension board	5322 216 51153

15.6 ELECTRICAL PARTS

The opening of parts, or removal of covers, is likely to expose live conductors. The instrument should therefore be disconnected from all voltage sources before any opening of parts or removal of covers is started.
During and after dismantling, bear in mind that capacitors in the instrument may still be charged even if the instrument has been separated from all voltage sources.

16.0 ACCESSORY INFORMATION

16.1 ACCESSORIES SUPPLIED WITH THE INSTRUMENT

16.1.1 Passive probe with automatic range indication

For operating or service information refer to the separate booklet, supplied with the probes.

16.1.2 Blue contrast filter

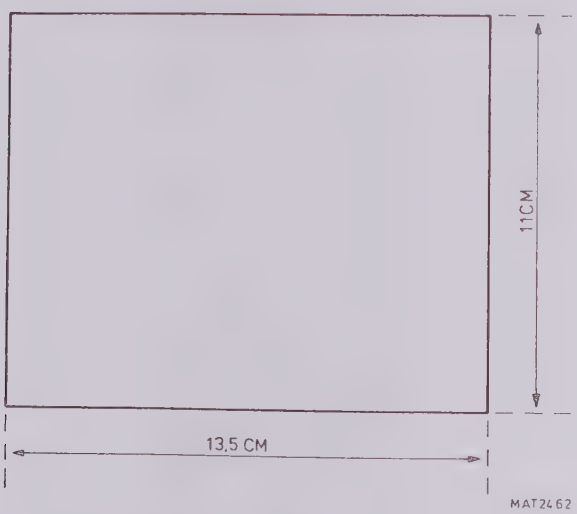

Figure 16.1 Blue contrast filter. (Factory installed !)

16.1.3 Front cover

Figure 16.2 Oscilloscope with front cover.

16.2 OPTIONAL ACCESSORIES

16.2.1 IEEE-488/RS232-C bus interface PM8956A

The interface is a general-purpose bus interface designed according to the IEEE-488/RS232-C standard. This option can be either retrofitted or factory installed. It enables the oscilloscope to be used in a measuring system together with other IEEE-488/RS232-C bus compatible instruments.

For more detailed installation, operating or service information concerning this facility, refer to the separate manual:

IEEE-488/RS232-C BUS INTERFACE PM8956A

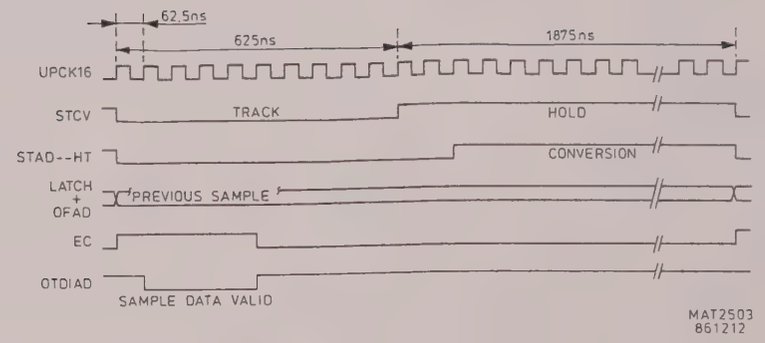

Figure 8.11.1 Timing diagram of the ADC and T&H unit.

NOTE: The STCV signal is derived from the CKCDOC-1 signal on unit A33. The CKCDOC-1 signal is derived from UPCK16 on unit A5. So there is a determined time relationship between the STCV signal and the other control signals on this unit.

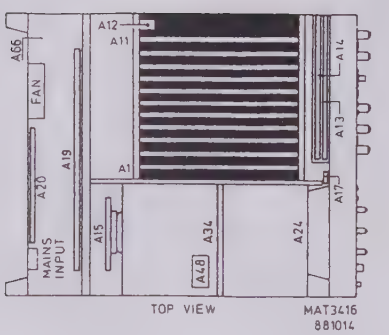
UNIT A12 - MOTHERBOARD



CONTENTS

8.12.1 General information..... 8.12-1
8.12.2 Detailed information..... 8.12-1
8.12.3 Primary bus (CCU-bus)..... 8.12-2
8.12.4 Description of the primary bus signals..... 8.12-3
8.12.5 Secundary bus..... 8.12-4
8.12.6 Additional motherboard connections..... 8.12-14

8.12.1 General information

The function of the motherboard unit is to interconnect the various plug-in units with each other as well as with the rest of the system.

8.12.2 Detailed information

No active components are mounted on this board.

Each plug-in unit is provided with one or two (three row) 96-pole EURO-connectors. One connector is used for the primary or CCU (Central Control Unit) - bus. The other connector is used for the so-called secundary - bus.

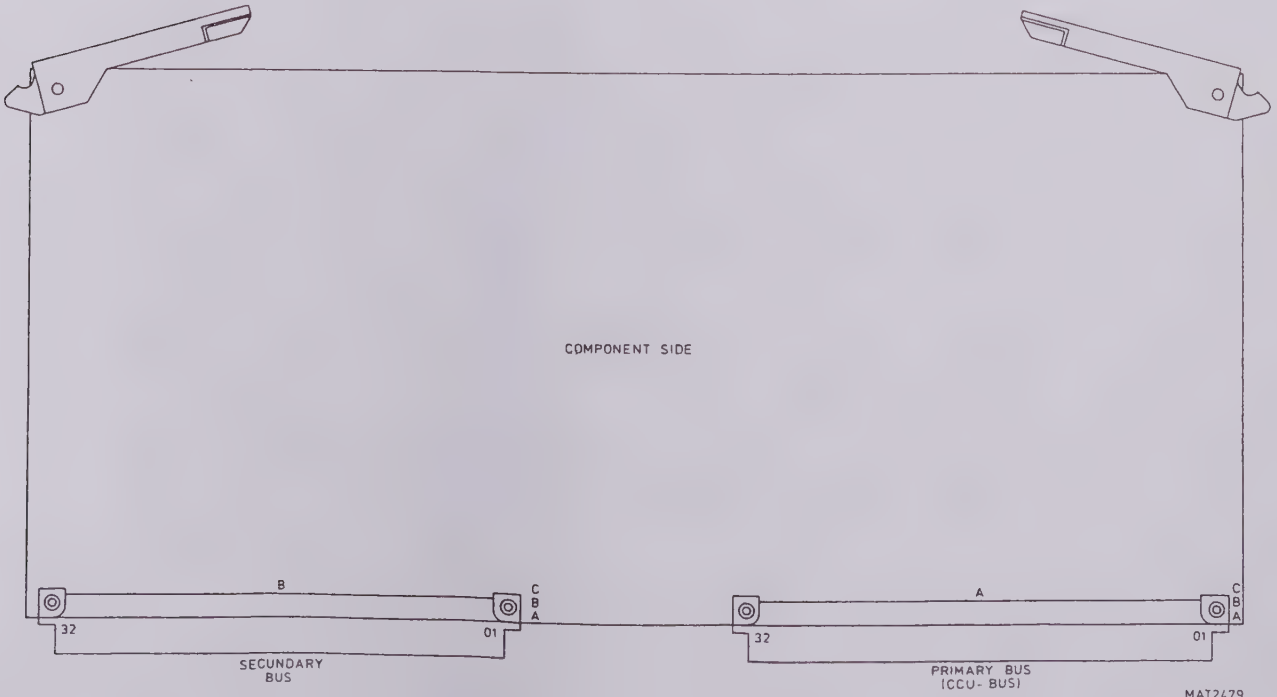


Figure 8.12.1 EURO-connectors.

8.12.3 Primary bus (CCU-bus)

This is a description of the pin lay out for the connectors of the CCU-bus on the motherboard.

8.12.4 Description of the CCU-bus signals

a1, b1 and c1	: 5 V digital
a3, b2, b3 and c3	: Ground of the digital 5 V
a30, b30 and c30	: Analog earth
a31, b31 and c31	: Analog -7 V
a32, b32 and c32	: Analog 7 V
a2	: 8MHz processor clock
a5	: Memory select down. This line indicates that the chip select of the RAM´s must be disabled on battery back up.
a6	: Voltage for the battery back up RAM´s
a7	: Battery voltage
a8 ... a14	: Lowest 7 address lines
a15 ... a22	: I/O select lines for the selection of the input/output ports
a23 ... a29	: Interrupt level lines. The sequence is as follows: ILØ1--LT --> 40 ms interrupt ILØ2--LT --> DPU interrupt ILØ3--LT --> rotary interrupt ILØ4--LT --> option interrupt ILØ5--LT --> display interrupt ILØ6--LT --> delta-t interrupt ILØ7--LT --> power down interrupt (increasing priority)
b4	: Memory select for the microprocessor RAM
b5	: Memory select for the display memory
b6	: Memory select for the DPU programm memory
b7	: Memory select for the options
b8 ... b21	: Address lines 8 ... 21
b22	: Not used
b23	: Not used
b24	: Not used
b26	: Not used
b27	: Not used
b28	: Watch dog trigger line. Masters can trigger the watchdog via this line.
c2	: 16 MHz clock from the microprocessor unit.
c7	: Microprocessor reset output.
c8	: Data transfer acknowledge. This is an open collector line on which units, which are addressed via MYSLØ1 ... MYSLØ4, can indicate that the data on the data bus is accepted or stable.
C9	: Data lower strobe. With this line active, the lowest 8 data bus lines can be used for read or write actions.
c10 ... c25	: Databus
c27	: Data higher strobe. With this line active, the highest 8 data bus lines can be used for read or write actions.
c28	: Microprocessor read.
c29	: Microprocessor write.
c30	: Z modulation frequency of 200 kHz.

8.13.1 General information

This front unit contains the front-panel pilot lamps, soft-switches and soft-switches with built-in pilot lamps.

8.13.2 Pilot lamps

The front panel pilot lamps are controlled by the microprocessor via the data bus lines DBØØ ... DBØ7 and latches D4206 and D4207.
Each latch can be activated by an output signal from the decoder D4204. This decoder decodes the three microprocessor address bits ABØ1, ABØ2 and ABØ3 and is enabled by the signals ABØ4, UPWR--LT and IOSLØ4LT.
This is done when the microprocessor generates the front unit addresses and the UPWR--LT signals for the control of the pilot lamps.
Latch D4206 controls the pilot lamps DOTS, SMOOTH, NEGATIVE SLOPE, EXT CLOCK, ALIASED, REP ONLY and NOT TRIG'D.
Latch D4207 controls the pilot lamps UNCAL A, UNCAL B, REMOTE, X-EXPAND UNCAL, LOCK and WRITE.

8.13.3 Front-switches

The settings of all the front-switches are periodically read by the microprocessor system.
The front-switches are therefore placed in a matrix structure.
Eight switches at a time can offer their settings to the inputs of data buffer D4203.
Each row of eight switches can be activated by one of the output signals CNØØ ... CNØ6 from the address decoder D4201. These signals are on a -0,7 V level because of the -0,7 V level on input 3 of D4201. In this way the 0,7 V accross the diodes is compensated and the signals RWØØ ... RWØ7 are brought on a 0 V level.
This decoder decodes the three microprocessor address bits ABØ1, ABØ2 and ABØ3 and is enabled by the signal combination ABØ4, UPRD--LT and IOSLØ4LT.
This combination resulting in signal ENFTSWLT is generated when the microprocessor generates the front unit addresses and the UPRD--LT signals for the reading of the soft-switch settings.
When signal ENFTSWLT is active, front switch buffer D4203 will place the matrix data RWØØ ... RWØ7 on the data bus lines DBØØ ... DBØ7.
The matrix is scanned by the microprocessor, every 40ms.

8.13.4 Address decoding table

The addresses which are generated by the microprocessor are decoded by address decoders D4204 and D4201 according to the following table.

IOSLØ4LT	ABØ4	ABØ3	ABØ2	ABØ1	Function WR	RD
0	0	0	0	0	Leds (4206)	CNØØ
0	0	0	0	1	Leds (4207)	CNØ1

8.14.2 Optical switches

The rotation of an optical switch is detected by the two internal photo-transistors. If the control is turned from one position to another, light from the infra-red LED's falls in the photo-transistors, pulsed via the holes in a perforated disc. As a result, the photo-transistors conduct for some time and their collectors are low.

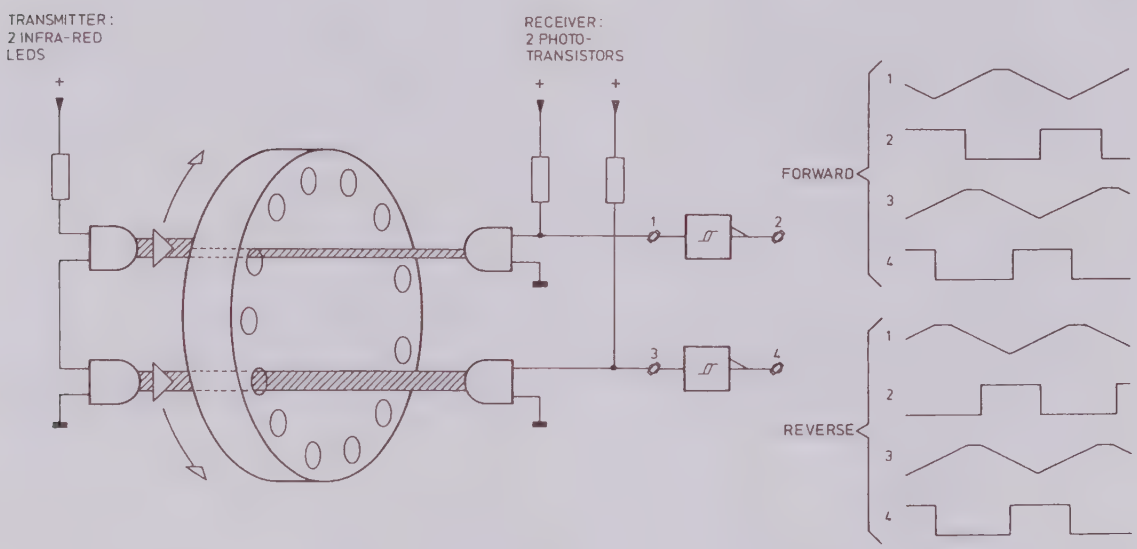

Figure 8.14.1 Optical switches MAT 2481

The collector signals of the photo-transistors are applied to three 3-state registers D4012, D4011, and D4009 as rotate forward signals RTFWØ1 ... RTFW12 and rotate backward signals RTBWØ1 ... RTBW12. This is done via SCHMITT-trigger inverters for good pulse definition.

If one of the optical switches is operated, the relevant RTFW.. pulse is used for the generation of an interrupt level pulse ILØ3PU on output point 9 of NAND D4014 on each positive or negative going signal edge.
This pulse is used as clockpulse for the D-type flip flop D4016, resulting in an interrupt level signal ILØ3--LT which interrupts the microprocessor. This is done to realize a very quick reaction by the microprocessor when an optical switch is operated.

The flip flop output signal ILØ3--HT is used to clock the actual photo-transistor output levels in the three 3-state registers via the databus lines DBØØ ... DBØ7 for further processing.
In this way the microprocessor knows which switch is operated and in which direction.
The microprocessor will be interrupted by signal ILØ3--LT and generates in turn three different addresses and the UPRD--LT signals in order to read the contents of the 3-state registers.
If a front unit address is generated, the IO select signal IOSLØ4LT for the front unit will be active.

Selection of one of the 3-state registers is achieved then by decoder D4013, which decodes the three microprocessor address lines ABØ1, ABØ2 and ABØ3. This results then in one active low decoder output line (enable rotate) ENRTØ1, ENRTØ2 or ENRTØ3. This are the output enable signals for the three 3-state registers and the one which is enabled places its data on the microprocessor data bus lines DBØØ... DBØ7.
During the read cycle, flip flop D4016 will be set to its zero state again by signal ENRTØ1.

8.15.1 General information

This unit basically comprises a Z-demodulator circuit, a final Z-stage and a final focus stage.

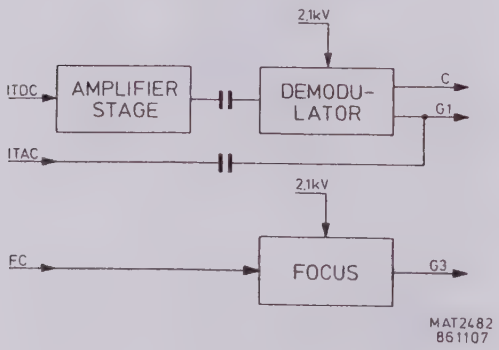

Figure 8.15.1 Blockdiagram final Z-stage.

8.15.2 Final Z-stage

The high frequency component ITAC of the Z-signal is fed via a high voltage capacitor C2806 to the high voltage part of the circuit.
The modulated low frequency component ITDC of the Z-signal is fed via a high voltage capacitor C2803 to a demodulator circuit in the high voltage part of the circuit.
The resulting demodulated signal is then combined with the high frequency component from C2806 and applied to the intensity grid G1 of the C.R.T.

8.15.3 Final focus stage

The focus signal FC is applied to the final focus stage brought on a correct level and applied to the focus grid G3 of the C.R.T.

8.16.1 General information

The C.R.T. CONTROL unit, which is located below the C.R.T., contains the frontpanel C.R.T. controls:

- FOCUS
- INTENS TRACE
- INTENS TEXT
- ILLUM
- TRACE ROT

The FOCUS level FCIN is applied to the focus circuit on unit A1.

The INTENSITY levels ITTR and ITTX are applied to unit A1 and depending on the current display block (trace or text) one of these two (trace or text) levels will be selected and applied to the Z-amplifier.

8.16.2 Signal name list

Signal name	Description	Signal source	Signal destination(s)
FCIN	Focus input	A16	A1
ITTR	Intensity trace	A16	A1
ITTX	Intensity text	A16	A1
TRRT	Trace rotation	A16	C.R.T.

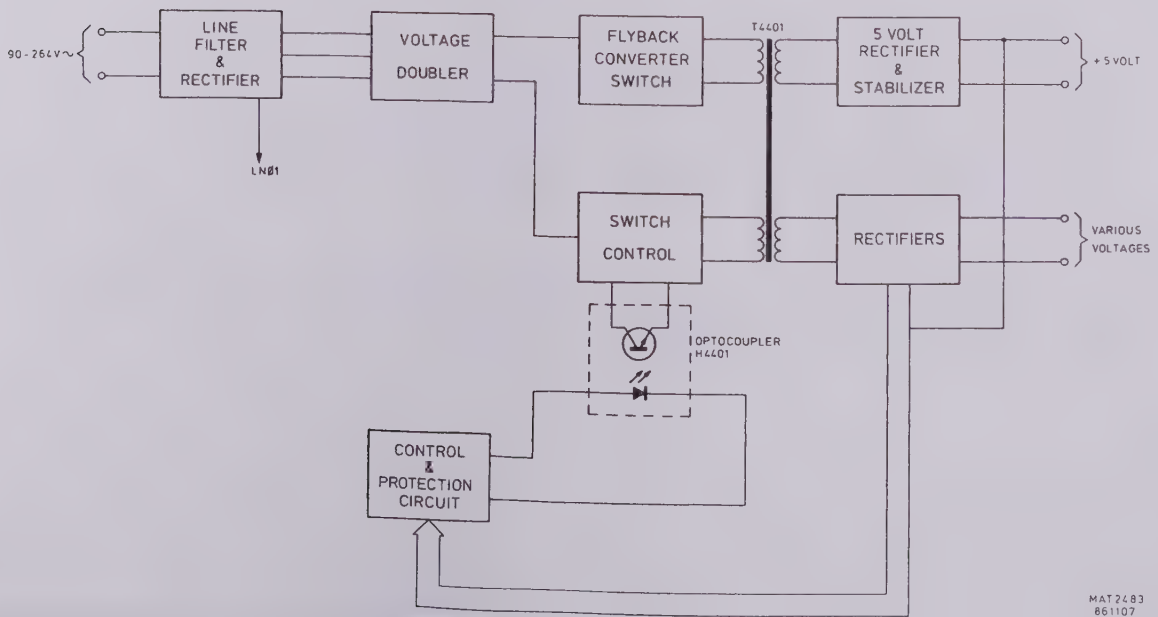
8.19.1 General Information

WARNING: The complete circuit is at mains potential up to transformer T4401 and opto-coupler H4401. To avoid any electrical shock, it is strongly recommended to read section 10.1 first.

The block diagram below shows the parts of this unit.



The line voltage is applied via a line filter and a rectifier to a voltage doubler. The voltage is only doubled if the line voltage is below 140 V.
The output voltage of the voltage doubler is applied to transformer T4401 via a flyback converter, which consists of a flyback converter switch and a switch control circuit.
The switch control is influenced by the control and protection circuit via opto-coupler H4401. The latter and transformer T4401 perform a galvanic separation of the instrument from the line voltage.
The various output voltages of transformer T4401 are controlled by the control & protection circuit, which gives protection against over- and undervoltage and a too high temperature.
The +5 V for the digital circuitry has a separate stabilizer.
When the power is on, the POWER ON led on the front panel lights. This led is connected to +7 V on the CRT control unit A16.

8.19.2 The Mains filter and rectifier

The mains input (90 V...264 Vac) is filtered by a mains filter, consisting of C4401 and L4401 and fed into a full bridge rectifier (V4401...4404).
Resistors R4402 and R4403 have a surge current limiting function.
A capacitive network C4402...C4407 across the input serves to reduce interference, the centre-point being coupled to earth to provide electromagnetic compatibility. C4403 and R4401 provide a trigger pick-off point LNØ1 for LINE triggering.

8.19.3 The voltage doubler

To avoid the flyback converter switching high currents a voltage doubler has been provided. This doubler is switched off at high input voltages.
The principle of the voltage doubler is given in figure 8.19.2.

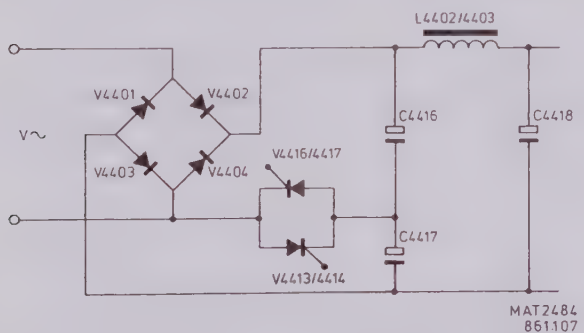


Figure 8.19.2 Simplified diagram of the voltage doubler.

The thyristors are turned on if the output voltage of the doubler is below 200 V approx. (double output voltage).
They are turned off if the output voltage rises above 400 V approx.

If the thyristors are off, the ac-voltage charges the series connection of C4416 and C4417 to the peak value. The voltage on both capacitors is smoothed by L4402/4403 and C4418.

If the thyristors are on, the positive phase of the ac-voltage charges C4416 via V4402 and V4416/17 to the peak value.
The negative phase charges C4417 via V4401 and V4413/4414 to the peak value.
The voltage on the series connection of C4416 and C4417, which is twice the peak voltage of Vac, is smoothed by L4402/4403 and C4418.

The thyristors are switched on and off by a schmitt-trigger circuit consisting of V4406/4408, V4407 and their associated components.

8.19.4 The flyback converter switch (see also figure 8.19.3)

The switch consists of a power transistor V4429, connected in series with diode V4419. The transistor is switched by 2 MOSFETS V4424/V4426, which are controlled by the switch control. By regulating the on and off periods of the switch, the output voltages of T4401 are controlled. The other components of the switch serve as a dV/dt limiter to decrease the switching dissipation, to reduce interference and to protect the switching transistors against overvoltages.

8.19.5 The switch control

The switch control is a rather complicated circuit, which will be explained by the simplified circuit diagram of figure 8.19.3.
After power on, a current via R4434/4436 and the b-c diode of V4433 charges C4423 until the treshold voltage of the FET is reached, after which the converter switch turns on. The current through winding 1-2 of T4401 and R4448...R4452 increases linearly and charges T4401.
This causes a linearly increasing voltage on winding 3-4, which turns the converter switch further on.
This is the forward stroke.

If the voltage over R4448...R4452 rises above 1,2 V the cathode-gate voltage of thyristor V4441 rises above 0,6 V and it will be fired.
The NTC resistor R4444 provides temperature compensation for the firing point of the thyristor.
Now the converter switch is blocked and the flyback stroke starts, during which the secondary windings of T4401 discharge via the rectifiers into the smoothing capacitors.
In this situation winding 3-4 of the transformer gives a negative voltage, which charges C4423 as indicated. The output voltage of V4433 will be zero, so the thyristor extinghuishes.

If the transformer is discharged, the output voltage of winding 3-4 drops to zero and C4423 supplies a positive voltage to V4433, which will turn the converter switch on. The forward stroke starts again and so on.

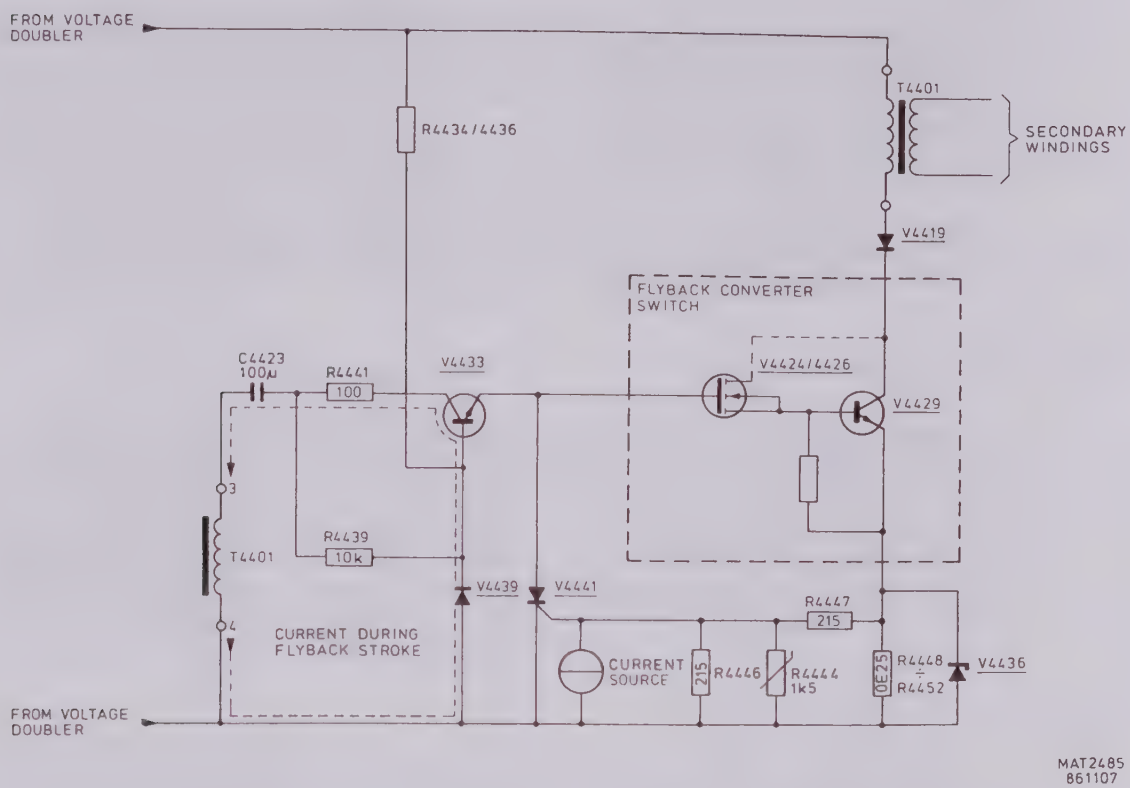

Figure 8.19.3 Simplified diagram of the flyback converter switch.

V4433, R4439 and V4439 form a voltage stabilizer circuit during the forward stroke, which limits the voltage on the gates of the MOSFETS to 15 V. The switching frequency varies from 20 kHz to 40 kHz, depending on the input voltage.

By inserting a current in R4446 with a current source, the on/off time of the converter switch (duty cycle) can be influenced. This is used to control the output voltages of T4401.
The current source is realised with opto-coupler H4401, which is supplied by C4424. This capacitor is charged during the forward stroke via V4438.
The opto coupler is controlled by the control and protection circuit.

If one or more of the transistors of the converter switch are blown, the zenerdiode V4436 prevents the burning out of R4448...R4452 and the whole switch control circuit, because it blows itself and makes a short circuit over R4448...R4452.
Afterwards, the mains fuse will blow.
If, after having replaced the converter switch transistors and the mains fuse, the power is turned on again, the thyristor V4441 can't be fired due to the short circuit of V4436. In consequence the converter switch won't be turned off and the TRANSISTORS and MAINS FUSE will BLOW AGAIN.

WARNING: Replace always zenerdiode V4436 after having replaced one or more converter switch transistors (V4424, V4426 and V4429) and the mains fuse.

8.19.7 The protection circuit

The protection circuit gives the protection against:

- overvoltage on +5D
- overvoltage on +14 V
- too high temperature
- undervoltage on -7 V

The signal C-ON serves as a power supply for this circuit.
Overvoltage on +5D or on +14 V makes V4476 conducting. A too high temperature (e.g. caused by a failure of the fan) also makes V4476 conducting, due to the effect of PTC R4469.
V4476 makes V4474 conducting and via R4459 both transistors keep themselves conducting.
Now V4474 supplies a high current into the opto-coupler, which makes the forward stroke very short and eliminates the overvoltage.

If there is a short circuit in one of the voltage on the secondary side of the transformer all voltages will drop, the -7 V inclusive. This causes V4473 to conduct, due to a voltage rise on the node V4471, R4461, V4472. Next V4471 conducts, which makes the forward stroke very short. No components will be overcharged in this way, in spite of the short circuit.
To prevent the undervoltage protection being active immediate after power on, a delay circuit consisting of R4461 and C4461 is provided. After an over- or undervoltage detection C4461 is discharged fastly by the mains switch, which has a contact connected to connector X4402, when the oscilloscope is switched off.

8.19.8 The +5 volt stabilizer

The output voltage of winding 10-20 of transformer T4401 depends on the load of the +14 V, because this voltage is regulated by the control unit by means of the flyback stroke.
To get a stable +5 V power supply for the digital circuits (+5D) a stabilizer is provided, which works during the forward stroke (forward converter).
During the positive phase of winding 10-20 (the forward stroke), C4429 is charged via L4408, V4449 and L4409. The voltage on C4429 is smoothed by L4411/4412 and C4431.
During the negative phase (the flyback stroke), V4451 acts as a flywheel diode for L4409.
There also flows a current from +5D through V4486, and V4484 in the reverse direction through choke L4408. This demagnetises the core of L4408 or even magnetises it in the reverse direction, depending on the value of the reverse current.
During the forward stroke, the core of L4408 has to be magnetised again. The more the core has to be magnetised, the higher the self inductance will be and the lower the voltage on C4429 and C4431 will be.
A lower voltage on +5D causes the operational amplifier N4401 to give a higher output voltage. The transistor V4486 conducts less, the reverse current through choke L4408 and so the self inductance decrease and so the voltage on C4429 and C4431 rises.
RV10 serves as a reference voltage.

Figure 8.19.4 shows some wave-forms in the flyback converter.

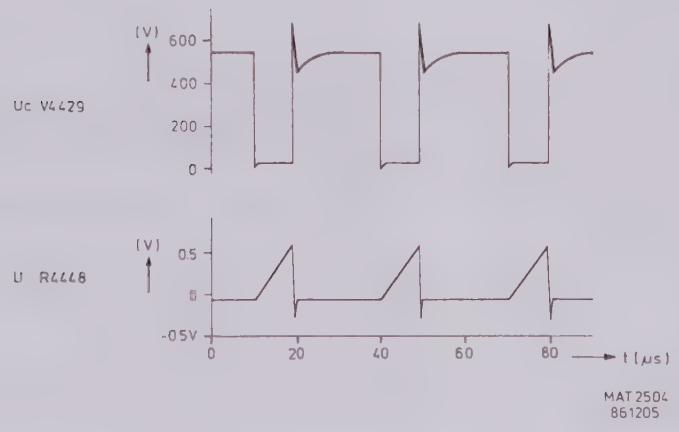

Figure 8.19.4 Voltage waveforms in the flyback converter.

8.19.6 The control circuit

This circuit consists of an operational amplifier (N4401) with some associated components.
The rectified and smoothed +14 V is fed back to the op-amp and compared with the 10 V reference voltage, RV10, which comes from unit A20.
If the +14 V is too high, the op-amp supplies more current into the opto coupler. Next, the opto coupler supplies more current into R4446, which causes the thyristor V4441 to be fired earlier. This shortens the forward stroke, so transformer T4401 is charged less. Next the flyback stroke will be shorter and the smoothing capacitors will be charged less and the output voltages, +14 V inclusive, decrease. So only the +14 V is regulated. All the other voltages are not regulated, except the +5 volt (+5D).
Because the output voltages depend on the length of the flyback stroke, the flyback stroke is regulated by the control circuit.
The +5D has a separate stabilizer, which works during the forward stroke (see 8.19.8)

Resumed:

- If the load on +14 V varies, the forward and the flyback stroke vary. The duty cycle remains constant; the frequency varies.
- If the input voltage varies, only the forward stroke varies; the flyback stroke remains constant. A higher input voltage results in a shorter forward stroke.
- The load on the +5D influences only the waveform of primary current through transformer T4401 during the forward stroke. The frequency and the duty cycle remain constant.

8.20.1 General information

This unit consists of several circuits:

- a reference voltage source
- a line trigger circuit
- a power down/up detection circuit
- an EHT converter
- a fan-control circuit

WARNING: To avoid any electrical shock, it is strongly recommended to read section 10.1 first.

8.20.2 The reference voltage source

The voltage source consists of an operational amplifier N4601 with the associated components.
The zenerdiode V4601 (6,5 V) serves as the reference voltage source for the op-amp.
Via diode V4602 the node R4601, R4602, V4602 is kept at a stable voltage of 9,4 V to achieve a stable current through zenerdiode V4601.
The output voltage RV10 can be adjusted with R4607.

8.20.3 The line trigger circuit

The LNØ1 input from POWER UNIT 1 (A19) is a mains-voltage related signal. To ensure that the line trigger signal has a constant amplitude, this circuit provides automatic gain control. The LNØ1 input is fed to a feedback operational amplifier N4601 with a gain of 1000 (R4636/R4637). The output LN on pin 14 is fed to a comparator input N4601-10. The other input carries a reference voltage. This stage operates as a top detector. The output on pin 8 is a rectangular waveform (+14 V ... -14 V) with a very short duty cycle. The long negative stroke of this voltage charges C4618. The short positive stroke, which width is dependent on the amplitude of the sinewave on N4601-10, discharges C4618 a bit. The voltage on C4618 serves as a control voltage on the gate of the FET V4617. This FET conducts to regulate the amplitude of the signal on N4601-12.If, for instance, the mains voltage increases, LNØ1 also increases.
Then output N4601-14 increases. As a result the pulse width of the square wave signal on N4601-8 will get wider and C4618 will be charged less negative. FET V4617 will conduct more, which decreases the sine wave signal on N4601-12. This results in a direct correction of the output sinewave on N4601-14. The output provides the constant LN signal (sine wave 10 Vpp), which is routed to the external trigger unit (A31).

8.20.4 The power down/up detection circuit

The circuit consists of two comparators (N4602) with their associated components.
After power on, the signal C-ON goes high (> 20 V). After a time delay of 0.1 sec, determined by R4644 and C4622, the ILØ7--LT goes high. This signal, which is routed to the microprocessor unit A6, tells the microprocessor that the power is on and it can start.
In case of a converter failure, the C-ON-signal goes immediately low, which causes the signal ILØ7--LT to go low with a very short time delay, because C4622 is discharged fast via R4643 and N4602. The microprocessor will stop.

NOTE: C4622 can't be charged via R4643, because N4602 has open collector outputs.

8.20.5 The EHT converter

Transformer T4601 forms with the various capacitive loads an LC resonance circuit, with an own frequency of approx. 60 kHz.
The circuit is every period charged by a thyristor circuit, consisting of transistors V4608 and V4612 (switched parallel resonance converter).
The thyristor circuit is fired on the negative peak of T4601-9 (see figure 8.20.1). On the negative peak of T4601 - 9, the capacitor C4609 is charged via V4603, R4616, R4618, the b-e junction of V4608 and diode V4607. This fires the thyristor circuit.
Now V4611 charges the LC resonance circuit as soon as T4601 - 9 becomes positive, and V4608 discharges V4608.
When V4608 is discharged the thyristor circuit turns off, because the current from V4603 is below the treshold current of the thyristor circuit. Now C4608 is charged again via V4603.
A higher voltage at the base of V4603 results in a higher charge of C4608 and causes the thyristor circuit to be turned off later, so there will be supplied more energy to the resonance circuit, in this case the output transformer.
During the off-time of the thyristor circuit C4608 is discharged via R4616.

One output voltage (-2,1 kV) is fed back into op-amp N4601 to perform voltage stabilisation.
If the output voltage rises (i.e. -2,1 kV goes more negative) then N4601-3, N4601-1 and the emitter of V4603 go more negative. The on-time of the thyristor circuit will be shorter; the energy supplied to the transformer will decrease and therefore the output voltages will also decrease.

The output voltage F1/F2 (6,3 V) supplies the filament.
The output voltage of T4601-6 is rectified by V4613 and gives the -2,1 kV cathode voltage for the CRT and the feedback to N4601.
The output voltage of T4601-11 is converted to 14 kV in the HT-multiplier D4001 to supply the post acceleration anode of the CRT.
For security reasons the EHT ground is separated from the analogue ground on connector X4604 (1A, 1C, 2A, 2C) when the unit is removed.
The EHT is not available now (see also section 10.4).

The following figure gives some voltages in the circuit.

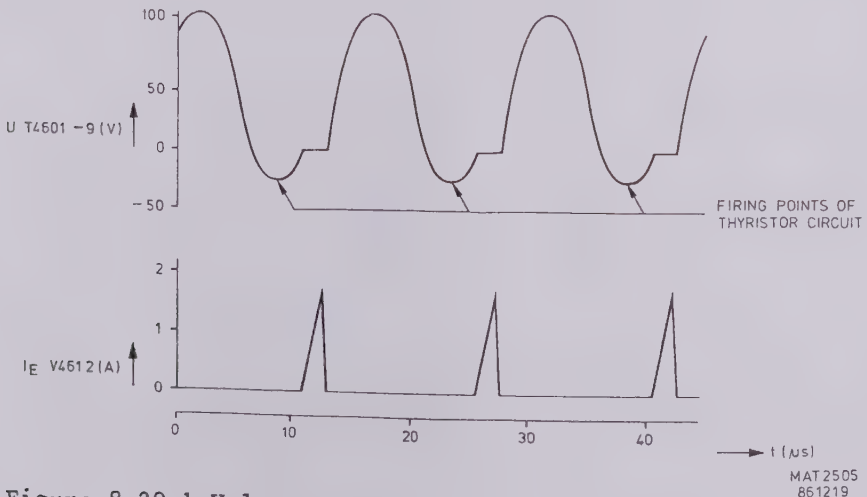

Figure 8.20.1 Voltage waveforms in the EHT converter.

8.20.6 The fan control circuit

In this circuit, a triangle wave voltage of 70 kHz is generated by comparator N4602. Resistor R4652 loads the open collector output. This triangle voltage is on N4602-5 compared with a voltage on N4602-4, which is influenced by a NTC resistor R4656 on this board.
The output voltage on N4602-2 is a square-wave signal, whose duty cycle depends on the temperature of the NTC. This square-wave switches via V4621 and V4622 a converter, consisting of L4601, V4619 and C4624, which gives a maximum voltage of 28 V. The output voltage is supplied to the fan and fed back to N4602-4 via V4618 to achieve an overvoltage protection for the fan.
If V4622 doesn't switch for some reason, the fan runs on 14 V via L4601, V4619 and L4602, which is mostly sufficient to keep the oscilloscope running.

8.24.1 Circuit description

The DRIVER UNIT buffers the sample and transport clock signals from the ACE, IC D6001 on the CCD LOGIC unit A26. The output signals drive the P^2CCDs on the P^2CCD unit A33.

As channels A and B are identical, only channel A is described.

The TRANSPORT CLOCK DRIVER A accepts the signals TCODA-HE and TCEVA-HE from the ACE.
The circuit around transistors V9401...V9404 splits both signals in 2 equal signals.
One set of these signals (TCOD2AHX and TCEV2AHX) is led via a 1 ns coaxial delay line (length approx. 22 cm) to a driver stage. The driver stage consists of the circuitry around transistors V9451...V9454, V9456 and V9457. It buffers the delayed signals TCODDAHX and TCEVDAHX.
The output signals TCODDALX and TCEVDALX are applied to the P^2CCDs.
The other set of signals (TCOD1AHX and TCEV1AHX) is applied directly to a similar driver stage, which consists of the circuitry around transistors V9551...V9554, V9556 and V9557.
The output signals TCODA-LX and TCEVA-LX are applied to the P^2CCDs.

The SAMPLE CLOCK DRIVER A buffers the sample clock signals SCODA-LE and SCEVA-LE from the ACE. It consists of the circuitry around transistors V9501...V9504, V9506 and V9507, which is similar to the transport clock driver stages.
The average DC level of the even sample clock is influenced by the signal SCOCA from the P^2CCD unit A33, to achieve an equal average DC level of the odd and even sample clocks.
The output signals SCODA-HX and SCEVA-HX are applied to the P^2CCDs via 75 ohm coax cables.

Note: A number of transistors are mounted topside down, which is marked with a dot at their emitters in the p.c.b. layout (see figure 8.24.1).

8.25.1 General information

On the management unit the following main functions are present:

1. - Decoupling of power supply voltages which are routed via this unit to units A32, A33 and A27...A30.
   - Interconnection of different power supply voltages which are routed to unit A34, A31 and A26.

2. - Interconnection for several control signal lines between different units e.g. via connectors X2516-X2502-X2503-X2513-X2514
   - Signal buffering of control signals e.g. via D434, D404 etc.

3. Interface between microprocessor and the following units:

Vertical signal unit	A32
P^{2}CCD unit	A33
Attenuators A and B	A27...A30
Clock unit	A34
External trigger unit	A31
CCD logic	A26

8.25.2 Microprocessor control- and data buffers and address decoder (D401, D402, D403, D406, D407)

The bi-directional 16-bits data information is fed from the microprocessor via data buffers D401 and D402 to unit A25 and A26 (via X2504).
The data buffers D401 and D402 are enabled by the control signal ENBS derived from D414-D416-6 which on its turn are controlled by the control signals IOSLØ6LT and IOSLØ7LT.
The control signal RDDABS (read data buffers) which is derived from the signals UPRD-1LT and IOSLØ7LT changes the direction of data transport.
If this RDDABS signal is low the contents of the data buffers is read by the microprocessor and if it is high, the buffers will receive data from the microprocessor.

The address signals ABØ1...ABØ4 and the control signals UPRD--LT and I/O select Ø6 and Ø7 are controlling the functions on this unit via the address-control buffer D403.
The signal IOSLDL enables the buffer D403 and freezes ABØ1...ABØ4, I/O select Ø6 and Ø7 and UPRD--LT after a fixed I/O select delay time which is determined by D408-13-12-11-10.

This delay time of 50 ns is necessary to prevent interference on the address and control signals coming from the data bus when the data bus switches.

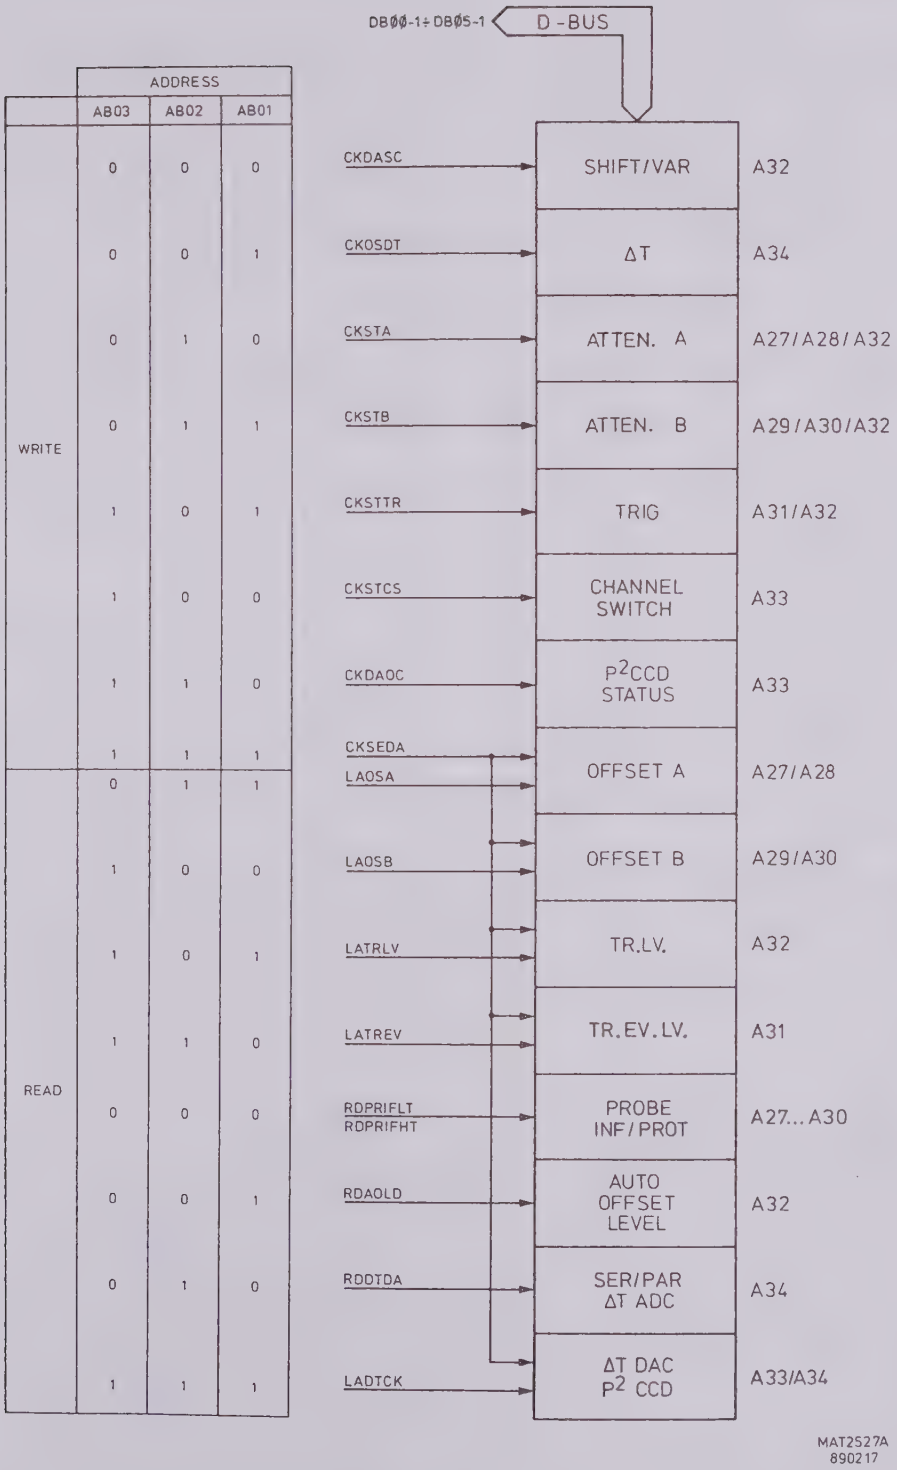

Figure 8.25.1 Address decoder control signals.

The control signals LAOSA, LAOSB, LATRLV, LATREV and LADTCK select the 14-bits serial DACs respectively N403, N404, N407, N406 and X2506-7.

8.25.3 Attenuator control latches (D409, D411, D412, D413)

In the truth tables below, the several control signal levels are indicated for the vertical attenuation control on the attenuator units and on the vertical signal unit.
The latches for channel A (D409 and D411) are selected by CKSTA and for channel B by CKSTB (see below). The drivers D414 and D416 are level adapters to adapt the TTL level to a 0-10 V level.
The control signals OSA+/- and OSB+/- are routed to D423 pins 13 and 5 to control the polarity of the offset of channels A and B.

For channel B the logic levels are exactly the same as for channel A only the addresses are different:

CKSTB and the latches for channel B are D412 and D413.

8.25.4 Vertical signal switch latch

This latch is controlled by the clock signal CKSTCS (pin 11).
This latch (D417) is used for control signals (PDSWØ...PDSW2) for the signal switch (unit A33) and for control of the bandwidth limiter and ADD circuit on the vertical signal unit A32.

8

8.25.5 Probe information ADC and 50 Ohm protection buffer (D437 and D419)

The selection of this detection IC D437 is done by RDPRIFHT coming from D407.
The detection of the attenuation factor of the connected probe is done via the current signal PRIFA-XA for ch. A and with PRIFB-XA for ch. B.
These signals from the attenuator units A28 (A) and A30 (B) are applied to pins 3 and 16 of D437.
This results in the following output signals from D437:

PROBE INDICATION

PROBE	CHANNEL A DB 00-1	DB 01-1	DB 02-1	DB 03-1	CHANNEL B DB 04-1	DB 05-1	DB 06-1	DB 07-1
1:1 (1 MOhm)	1	1	1	1	1	1	1	1
1:100 (1 MOhm)	1	1	0	1	1	1	0	1
1:10 (1 MOhm)	1	0	0	0	1	0	0	0
1:100 (50 Ohm)	1	1	0	0	1	1	0	0
1:10 (50 Ohm)	1	0	0	1	1	0	0	1
CURRENT PROBE								
HV ISOLATION PROBE	1	1	1	0	1	1	1	0

The selection of the 50 Ohm protection buffer is done by the signal RDPRIFLT.
This buffer latches 2 signals from the vertical attenuator units A28 and A30 (PT50A-LT and PT50B-LT), the aliasing status signal ALID and trigger status signal TRID.

These input signals are generating the following output data:

50 OHM PROBE PROTECTION

50 OHM PROBE PROTECTION CH A	PT50A--LT DB08-1
50 Ohm REED RELAY OFF	0
50 Ohm REED RELAY NOT OFF	1
50 OHM PROBE PROTECTION CH B	PT50B--LT DB09-1
50 Ohm REED RELAY OFF	0
50 Ohm REED RELAY NOT OFF	1

TRIGGER INDICATION

NOT TRIG'D	DB11-1 TRID
TRIGGERED	1
NOT TRIGGERED	0
ALIASED	DB10-1 ALID
ALIASED DETECT	1
NO ALIASING (NORMAL)	0

8.25.6 Trigger latches (D421 and D422)

The trigger and trigger events modes are controlled by signals coming from the trigger latches D421 and D422.
These trigger latches are addressed by the control signal CKSTTR applied to the inputs D421-11 and D422-11.
The output control signals TRDUMO and TREV+/- are routed to respectively the trigger level DAC and the trigger event level DAC.
The trigger latches generate the following output control signals:

TRIGGER INPUT AND TRIGGER EVENTS INPUT

TRIGGER COUPLING	ACTRCO	DCTRCO	HFTRCO
DC	0	1	0
DC/LF	0	1	1
AC	1	0	0
AC/LF	1	0	1
AC/HF	0	0	0

TRIGGER SOURCE	ETTR	ETTR/5	ETTR/50
EXT	0	0	1
EXT:10	0	1	0

EXTERNAL TRIGGER COUPLING	TRACDC	
AC	0	
DC	1	
TRIG.MODE	TRDUMO	TRTVMO
NORMAL	1	1
DUAL	0	1
TV	1	0
AUTO LEVEL	AULV

OFF	0	
EVENT/5	TREV/1	
ON	0	
OFF	NOT USED	
EVENT/50	TREV/10	
ON	NOT USED	
OFF	1	

8

8.25.7 Delta-t serial parallel converter (D424, D426, D428) and the delta-t control latch (D427)

In the serial parallel converter consisting of two shift registers D424 and D426, the serial data DTADDA coming from the delta-t ADC on the clock unit A34 is converted into parallel data signals DB00-1...DB09-1 which are applied to the databus.
The clock signal which is controlling this conversion is DTADCK, coming from clock unit A34.
If all data are latched, the status signal, DTADST applied to D428-12, becomes active.
This status signal makes IL06--LT (D428-2) active (low).

Now the microprocessor will read the data by enabling the delta-t serial parallel converter via the RDDTTA signal. This signal also resets IL06--LT.

The signals DB15-1, CKSEDA and LADTCK are applied to the clock unit A34, where they are used for the delta-t ADC.

The delta-t control latch D427 is controlled by the clocksignal CKOSDT. The output signals behave as follows:

EN200MLT is 0 in time-base settings:
0,2 ms/div...0,5us/div
50 ns/div... 5ns/div
EN200MLT is 1 in all other time-base settings.

EN250MLT is 0 in time-base settings 200 ns/div and 100 ns/div.
EN250MLT is 1 in all other time-base settings.

CDOGC1 is 0 in the following settings:
360 s/div...200 ns/div, single channel, min/max off
0,2 ms/div...200 ns/div, dual channel, min/max off
CDOGC1 is 1 in all other settings.

CDSGC1 is 0 in the following settings:
360 s/div...5 ns/div, single channel, min/max off
0,2 ms/div...5 ns/div, dual channel, min/max off
CDSGC1 is 1 in all other settings.

CDOGC2 is 1 in time-base settings 200 ns/div and 100 ns/div.
CDOGC2 is 0 in all other time-base settings.

CDSGC2 is 0 in time-base setting 100 ns/div.
CDSGC2 is 1 in all other time-base settings.

8.25.8 Shift and variable control circuits

The shift and var-control circuits consist of the following parts:

* The shift-var latches
* The shift-var DAC
* The shift-var timer
* The shift-var decoder
* The sample and hold circuits.

* The shift-var latches (D429 and D431)

The latches D429 and D431 are controlled by the clock signal CKDASC from D406.
The output signals of the latches SCDBØØ...SCDB11 are the data for the shift-var DAC N401 (12 bits).

* The shift-var DAC (N401)

The 5V reference voltage for this DAC, coming from opamp N417-6 (adjustable with R462), is applied to N401-17. The setting time of the DAC circuit and N408, N409 is 1 ms.

The output voltage levels of the DAC circuits are as follows:

	INPUT DATA											OUTPUT
SCDBØØ	Ø1	Ø2	Ø3	Ø4	Ø5	Ø6	Ø7	Ø8	Ø9	10	11	
0	0	1	1	1	1	1	1	1	1	1	1	+5 V
.	.	.	.	.	.	.	.	.	.	.	.	.
.	.	.	.	.	.	.	.	.	.	.	.	.
0	0	1	0	0	0	0	0	0	0	0	1	+5 mV
0	0	0	0	0	0	0	0	0	0	0	1	0 V
0	0	1	1	1	1	1	1	1	1	1	0	-5 mV
.	.	.	.	.	.	.	.	.	.	.	.	.
.	.	.	.	.	.	.	.	.	.	.	.	.
0	0	0	0	0	0	0	0	0	0	0	0	-5 V

The dc output level of the DAC circuit is applied to the inputs of four sample and hold circuits N412...N416.

* The shift-var timer (D432)

This timer is necessary to determine the settling time for the DAC and the acquisition time for the sample and hold circuits.

These two delay times are determined by two separate timers:

1. D432-2-4 delay time ≃1 ms (settling time DAC-circuit)
2. D432-10-2 delay time ≃100 us (acquisition time S&H)

The first timer D432-2-4 is started by the clock signal CKDASC.
The delay time is determined by R458 and C492 (≃1 ms).
This time is necessary for the settling time of the DAC circuit. The second timer D432-10-12 is started ≃1 ms after the first one. The delay in this second timer is determined by R459 and C493 (≃100 us).
This time is necessary for the acquisition time of the sample and hold circuits.
The ≃1 ms delayed clock signal CKDASC is applied to the shift-var decoder (D433).

* The shift-var decoder (D433)

The decoder selects one of the four sample and hold circuits. The input signals SCDB12-1 and SCDB13-1 are decoded on receipt of a pulse coming from the second timer D432 into one of the four control signals:

Control signal	To sample and hold	SCDB12-1	SCDB13-1
TSSHA	N412	0	0
TSVGA	N413	1	0
TSSHB	N414	0	1
TSVGB	N416	1	1

* The sample and hold circuits (N412...N416)

The function of the sample and hold circuit is to take a sample from the DAC-output and to hold the sample (dc voltage) up to the moment that it will be refreshed by its control signal coming from the decoder D433.

TSSHA: Take sample for shift channel A
TSSHB: Take sample for shift channel B
TSVGA: Take sample for variable gain channel A
TSVGB: Take sample for variable gain channel B

If one of these control signals is active the stored dc value of the selected sample and hold circuit is given on its output.
The refresh rate of each sample and hold circuits is 20 ms (4x5 ms) see figure 8.25.2.

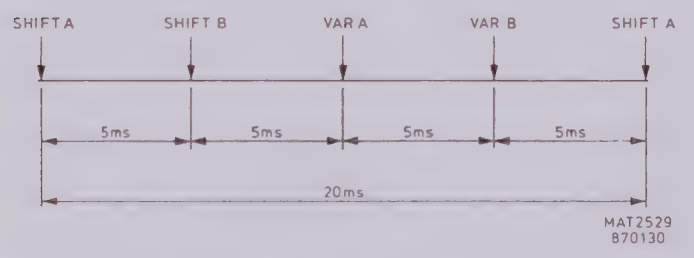

Figure 8.25.2 Refresh rate of each sample and hold (20 ms) and wait time (5 ms) before the next S&H is accessed.

8.25.9 Auto offset level ADC (N402)

The function of this ADC is to convert the average DC level of the input signal into digital data information to perform the auto offset function. This ADC (N402) is selected with the signal RDAOLD coming from D407.
The analog input signal, coming from vertical signal unit A32, is AOLD.
The reference voltage for the ADC is adjustable with R462 and stabilized by N417 and N411.
The signal conversion in the ADC is started by a low pulse RDAOLD (active low). The conversion time of the ADC is 20 us.
Next RDAOLD goes low again and the data is read by the microprocessor.

The following analog input levels result in:

INPUT ADC	OUTPUT ADC							
	DBØØ-1	Ø1	Ø2	Ø3	Ø4	Ø5	Ø6	Ø7
+5 V	1	1	1	1	1	1	1	1
.	.	.	.	.	.	.	.	.
.	.	.	.	.	.	.	.	.
+39 mV	1	0	0	0	0	0	0	1
0 V	1	0	0	0	0	0	0	0
-39 mV	0	1	1	1	1	1	1	1
.	.	.	.	.	.	.	.	.
.	.	.	.	.	.	.	.	.
-5 V	0	0	0	0	0	0	0	0

8.25.10 Offset and trigger level DACs (N403...N407)

The function of this part of the unit is to convert the digital offset and trigger level information into analog signals.

* Offset DAC A (N403)

This 14 bits serial DAC is controlled by the clock signal CKSEDA and the control signal LAOSA coming from respectively D406 and D407. The input serial-data DB15-1 is applied to pin 1.

The polarity of the OSA signal is determined by the OSA +/- signal, which determines if opamp N423 inverts or not.

From this 14 bits DAC, 10 bits are used.
The four LSB´s are always zero.

The offset is controlled as follows:

BINARY CODE															ANALOG OUTPUT
OSA+/-	MSB													LSB	
0	1	1	1	1	1	1	1	1	1	1	0	0	0	0	+5 V
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0 V
1	1	1	1	1	1	1	1	1	1	1	0	0	0	0	-5 V

The analog output level AOSA is via a coaxial wire applied to the offset adaption unit A50.

* Offset DAC B (N404).

This circuit is almost identical to the offset DAC A circuits, as described before.

The DAC is controlled by the CKSEDA and LAOSB signals.

The polarity of the output signal is determined by the OSB+/- signal.

The analog output level AOSB is via a coaxial wire applied to the offset adaption unit A50.

* Trigger event level DAC (N406)

This circuit is almost identical to the Offset DAC A circuit, as described before.

The DAC is controlled by the CKSEDA and LATREV signals.

The polarity of the output signal is determined by the TREV+/- signal.

The analog output level TREVLV is applied to the external trigger input A31.

* Trigger level DAC (N407)

This circuit is almost identical to the offset channel A circuit, as described before.

The DAC is controlled by the CKSEDA and LATRLV signals.

The analog output voltage is split up into two signal pathes:

TRDULV (level in dual trigger mode) and TRLV (trigger level in normal mode).
The polarity cannot be changed (output range 0...+5 V).
The analog signal TRLV can be switched off via D423-11-10, which is determined by TRDUMO.

TRDUMO

0 TRLV is switched off
1 TRLV is switched on

The analog output signals TRDULV and TRLV are applied to the vertical signal unit A32.

8.25.11 ACL buffer (D434), P^2CCD output control (D436) and P^2CCD buffer (D404)

* ACL buffer (D434)

The input signals of this buffer are coming from the P^2CCD unit A33 (via X2516) and the CCD logic A26 (via X2503).
The buffered output control signals are applied to the MRAM unit A5 via X2502.

* P^2CCD output control (D436)

This latch is selected by the clock signal CKDAOC.
The output signals are control signals for the P^2CCD unit A33.

Details of the control signals on the output of this latch are given in section 8.33.

* P^2CCD buffer (D404)

The two input clock signals CKCDOC and CK16ØØ are coming from the MRAM unit A5.
The buffered output clock signals are fed to the P^2CCD unit A33.
Details of these clock signals can be found in the sections 8.5 and 8.33.

8.26.1 General information

The CCD logic unit contains the logic which is used for controlling the P^2CCDs on unit A33. A part of the logic is fitted on the MINI CCD LOGIC unit (A49) which is fitted on this unit.

8.26.2 Circuit description

The AUTO TRIGGER logic causes the generation of the TDUF-2 signals when no triggers appear. The TDUF-2 signal is a derived trigger signal for the ACL.
The auto trigger logic is active when the AUTB signal is high, which will be assumed in the following description.
When HDOF at X2637 goes down, this is the sign of the ACL to start a new acquisition. Now pin 4 of D6008 gives a low pulse of 25 ms.
When TRSGØ1LT stays high, because no triggers appear, flip flop D6009 (the auto flip flop) receives a clock at the end of the 25 ms pulse at pin 11. The ENAURSLT signal goes low. Because it is fed back to pin 13 of D6007 further clock signals are blocked; the auto flip flop stays in this state.
The ENAURSLT signal sets flip flop D6009 via pin 4. The TRID signal, goes low, which is read by the microprocessor. This will light the NOT TRIG´D pilot lamp on the front panel.
In this situation pin 8 of D6009 is high and HDOF is low. Now EVUF goes high via R6402, D6011, D6007 and D6012. This generates on unit A49 the ENTDCNLE signal after one or two FSTB--HE pulses, depending on the DTPUSL signal. ENTDCNLE enables the trigger delay counter. Because ENAURSLT makes pin 3 of D6012 high, only the fast part of the trigger delay counter (the part in IC D6001 and IC D6022) counts down to generate TDUF-2 (see also the description of the trigger delay counter next).
The ENAURSLT signal enables RSAUFF on unit A49 to go high when a trigger occurs. This sets the auto flip flop D6009 at pin 10 via D6008, D6007 and D6011. Now ENAURSLT goes high, which is the starting situation.
When no triggers appear ENAURSLT stays low, which results in the generation of TDUF-2, every time when HDOF goes down.

When AUTB is low only flip flop D6009, which generates TRID, is enabled. TRID is set low by a clock from TDLD at pin 3.
If a trigger appears, TRSGØ1LT goes low, which resets the flip flop via pin 1; TRID goes high. If no trigger appears, TRID stays low. The microprocessor reads the status of TRID to control the status of the pilot lamp NOT TRIG´D.

The STAL signal is generated when HDOF is high and RSSW is low. (see also section 8.49.2 aliasing detection circuit).

The CCD LOGIC + FAST TIME BASE DIVIDER is integrated in an ACE (Advanced Customised ECL), IC D6001. It contains various fast dividers to generate the sample and transport clock from the FSCK signal in the P^2CCD mode and the Random Sampling mode.
It also contains the logic for the change over to the slow clock (SWCK) for the read out stroke in the P^2CCD mode and the random sampling mode. In the Direct (special) mode and in the Roll mode the sample and transport clocks are also derived from SWCK.
The DC-level of FSCK--XA controls the duty-cycle of the signals inside the ACE.

The TRIGGER DELAY COUNTER consists of a 25 bit counter. The first 5 bits are in the ACE (for speed reasons), the next 4 bits are in a fast Schottky TTL counter (D6022), the remaining bits are in 4 CMOS counters (D6026...D6029). Transistors V6008 and V6009 are a buffer. Each counter can be preset with a value which is stored by the microprocessor in the latches D6033...D6037. The latches for the counter stage in the ACE are integrated in the ACE.
When the slower part of the trigger delay counter (D6022 andD6026...D6029) has counted down the TDTC---LT is generated. This is inside the ACE combined with the status of the high speed counter stage. As soon as this stage has counted down, the TDUF-2 signal goes high.

The EVENTS COUNTER consists of a 16 bits counter (D6016...D6019). It can be preset with a value, which is stored by the microprocessor in the latches D6031 and D6032. The EVSG--HE signal represents the events signal that can be connected to the EVENTS/EXT CLK BNC input on the frontpanel. It is converted to TTL level by the circuitry around transistor V6001...V6004. The output
signal of this circuit (ETCK-2) clocks the events counter and is also applied to the acquisition control logic (unit A5). This path is only effective when an external clock is selected.
The counting down of the events counter is enabled by the ENEVCNLT signal. When the events counter has counted down the EVUF signal is generated.
Both the events counter and the trigger delay counter are preset by the TDLD-1LT signal.
During the signal acquisition stroke in P^2CCD-mode the trigger delay counter counts down after a preset caused by the going low of TDLD (pin 33 of X2602).
During the zero acquisition stroke in P^2CCD-mode the trigger delay counter counts down after a preset caused by the going low of RSSW (pin 28 of X2602).
Interference caused by the trigger delay counter will be eliminated during the digital substraction for leakage correction in the DPU (see also section 8.33).

The CONTROL LATCH latches various control signals from the microprocessor for this unit and unit A49.

The ADDRESS DECODER decodes various addresses which are used to clock the information from the microprocessor in the right latches.

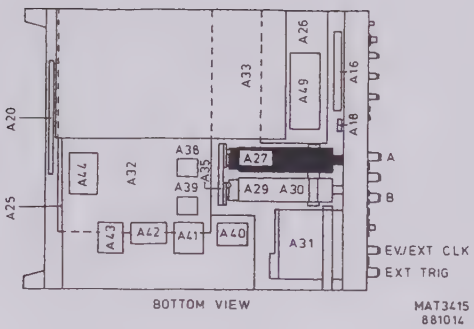
UNIT A27(A29) - HF VERTICAL ATTENUATOR



CONTENTS

8.27.1 Introduction..... 8.27-1
8.27.2 Circuit description..... 8.27-1
8.27.3 Signal name list..... 8.27-3

8.27.1. Introduction

The A and B channel attenuators are identical: so only A is described. Every attenuator module consists of two printed circuit boards:

- the h.f. attenuator unit
- the l.f. attenuator unit (see section 8.28)

The signal names in this description and in the circuit diagram between brackets are valid for the attenuator of channel B.

8.27.2 Circuit description (see figure 8.27.2)

The input signal from the Y BNC connector (A or B) is divided into five paths:

- three identical a.c.-coupled h.f. signal paths with different capacitive attenuation factors
- a 50-Ohm termination path
- a direct-coupled signal path to the l.f. attenuator unit A28 (A30)

The h.f. signal paths and the 50-Ohm termination are selected by the contacts of reed relays mounted on the l.f. unit and controlled by buffer D6903 (see figure 8.28.2.). This buffer is controlled by the Management unit A25 via the adaption unit A35.
Dealing first with the 50-Ohm termination, the reed relay contact connects the input signal across 50-Ohm (an array with two 100-Ohm resistors connected in parallel to earth). The array includes a temperature sensor which activates a temperature-sensing circuit (N6803) if the input signal exceeds 5 V.
The three h.f. paths are a.c.-coupled via C6809 (1x range) and C6814 (0.1x range), C6801 (0.01x range) which form part of the RC attenuators. The attenuator stages are each followed by a FET impedance converter stage (V6806 in the 1x path). A diode clipper in the gate circuit of the two lower ranges protects the input source follower of the impedance converter from excessive input voltages.

The impedance converter is switched by a PNP transistor (V6807) in its drain circuit. A +5 V switches it off and a +4,2 V switches it on.
The signal is then coupled via a diode (V6812) to transistor V6829, part of a summation stage (where also the l.f. signal is added, LFXA (B) via V6836 and V6833.
The truth-table of the input relay contacts is given in section 8.28.2.
When "0" coupling is selected, (ZEA-Hx ZEB-Hx active high) transistor V6828 takes over the current which is normally drawn by one of the coupling diodes (V6811 or V6812) in the h.f. path. This serves to maintain the circuit in d.c. balance.
Signal ZEA-Lx (ZEB-Lx) is routed to the LF attenuator to switch off the d.c. signal path.
The gain of the summation stage is determined by the ratio of its collector resistance to its emitter resistance, $\frac{Rc}{Re}$.
In the xl position, the collector resistance of V6829 is R6851 + (R6850//R6863), switched by V6819.
Switching is achieved by the logic level applied to the base of V6826; 0 V selects the xl range, +5 V selects the x5 range (x5 range not used).
The output signal from the summation stage V6829 is routed to the output amplifier with V6837 and V6839. The output signal from this amplifier is routed to the vertical signal unit A32 via a coaxial cable. A part of the output signal is routed to the feedback loop on the l.f. attenuator unit, HFXA(B), for LF and d.c. compensation.

There are three auxiliary circuits on the HF attenuator unit:

- Multiplexer D6801 for h.f. attenuator switching
- Window discriminator for 50-Ohm terminator protection (N6802)
- Temperature sensing circuit for 50-Ohm input termination (N6803)

Multiplexer D6801 is controlled by the signals ATSW0A(B) and ATSW1A(B) to select the xl, x10 and x100 capacitive attenuators, on pins 12, 14 and 15 respectively. These pins are connected with V6807/base, V6816/base and V6802/base.
The xl and x5 ranges are also selected by switching 0 V or +5 V to V6826/base (x5 range is not used). These voltages are made by multiplexer D6801/3, 4 and voltage divider resistors R6871 and R6862.

The window discriminator checks the voltage across the h.f. attenuator output by means of two operational amplifiers N6802. One detects the positive signal peak and the other detects the negative signal peak. The resultant outputs are summed, and if the input voltage of 5 V is exceeded during this measurement, the summation amplifier N6802/8, 9, 14 switches off transistor V6842. This gives a logic high PT50A-LT (PT50B-LT) (unsafe) signal to the central microprocessor. In this situation it is not possible to switch from 1M-Ohm to 50-Ohm input impedance.

A temperature sensing circuit of operational amplifier N6803. The temperature of the 50-Ohm termination resistor is measured by a 1 k-Ohm resistor, present in the OM545, with a temperature coefficient of +0,75 percent per degree Celcius. If the temperature gets too high, operational amplifier input N6803/2 goes high and switches V6846 on.

V6846 switches resistor R6890 between the probe indication line PRIFA-XA (PRIFB-XA) and earth. The central microprocessor knows that either a high-ohmic probe or a 50-Ohm overload is present now. The detection between the two is done as follows:

- The window of the discriminator is changed from 5 V to 25 V in combination with the x0,01 attenuator section, via a low level from op-amp output D6803/1 applied to the window discriminator via diode V6843 and switching FET V6841.
- The microcomputer switches the x0,01 attenuator section on for a moment and looks at the discriminator output (PT50A-LT(B): if the output is low, the voltage across the 50-Ohm resistor is between 5 and 25 V and the current through the 50-Ohm resistor is such that it can be switched off. With the discriminator output being high, the voltage is above 25 V and the current through the 50-Ohm resistor is too high to be switched off. Now a warning becomes visible on the C.R.T. of the instrument.
- Some seconds after having switched-off the 50-Ohm resistor, the microprocessor looks again to the probe indication line PRIFA-XA (PRIFB-XB). The temperature-sensing resistor is cooled down again and the probe indication line must be free again; if not, the microprocessor knows that it was not a 50 Ohm overload but that a high-ohmic probe is connected.

CONTENTS

8.28.1 Introduction..... 8.28-1
8.28.2 Circuit description..... 8.28-1
8.28.3 Signal name list..... 8.28-3

8.28.1 Introduction

The A and B channel attenuators are identical: so only A is described. Every attenuator module consists of two printed circuit boards:

- the h.f. attenuator unit (see section 8.27)
- the l.f. attenuator unit

The signal names in this description and in the circuit diagram between brackets are valid for the attenuator of channel B.

8

8.28.2 Circuit description (see figure 8.28.2)

The function of the LF attenuator unit is to compensate LF signals and to prevent DC drift. Also the DC OFFSET is controlled in this unit. The l.f. or d.c. path is chosen by the AC/DC reed relay switch contact (K6901). When "0" input coupling is chosen, the FET switch V6904 is switched off by signal ZEA-LX (ZEB-LX) on its gate. Then FET V6903 switches the input to earth potential via V6909. The diodes V6901 and V6902 protect the switch V6903 against switch-off spikes. The signal on the d.c. path is fed to the operational amplifier N6901 together with the d.c. input (via R6909, HFXA/B).
Any difference in the comparator is applied to the summation stage LFXA(B) consisting of V6836, V6833 and V6829 (on the HF unit). Note that when added, the h.f. signal and l.f. and d.c. signal shown at the summation stage form a reconstituted version of the signal applied to the input.
Feedback capacitors in the operational amplifier N6901 ensure that the frequency response of the d.c. path matches that of the a.c. path. Feedback capacitor C6906 is always in circuit. The feedback capacitors C6907 and C6908 are switched into the circuit by the FET-switches V6906 and V6907. In the x0,1 attenuation position C6906 and 6907 are in circuit. In the x0,01 attenuation position C6906, C6907 and C6908 are all in circuit as feedback capacitance. The connection between the inverting input of operational amplifier N6901 and the output of the HF attenuator unit HFXA(B) is made via a network of switchable feedback resistors. The amount of resistors switched into the circuit by FET-switches depends on the attenuator setting.

The feedback resistance networks are:

x1 : R6909 (always in circuit)
x0.1 : R6909//R6912 switched by V6911
x0.01: R6909//R6912//(R6913//R6914) switched by V6911 and V6913

Via the switchable feedback resistor network also the OFFSET level [OSA-(OSB-)] is applied to the comparator N6901 via R6911, R6920, R6916 and R6922.
In this way vertical shift of the base-line is achieved.

The FET switches V6906, V6907 (to switch the feedback capacitors) and V6911, V6913 (to switch the feedback resistors) are controlled by D6901 which on its turn is controlled by the data bus signals ATSW0A(B) and ATSW1A(B).

The relays on the HF unit (K6902...K6906) and K6901 on this unit are controlled by the data bus via N6903. The truth-table is given below.

Relay contact:	K6901	K6804	K6802	K6803	K6801
Relay coil :	K6901	K6902	K6903	K6904	K6906
Output N6903 :	16	15	14	13	12
5 mV/div	X	X	H	H	L
50 mV/div	X	X	L	H	H
500 mV/div	X	X	H	L	H
"0"	X	X	H	H	H
"AC"	H	X	X	X	X
"DC"	L	X	X	X	X
50 Ohm	X	L	X	X	X

H: not active, relay contact open
L: active, relay contact closed
X: don't care

8.31.1 Introduction

This unit consists of two main circuits:

The EXT TRIG input and the EVENTS/EXT CLOCK input.

On this unit S.M.D.'s (Surface Mounted Devices) and "normal" components are used together on one p.c.b..
The handling of S.M.D.'s is described in section 12.3.1.

Via the EXT TRIG input the time base can be triggered externally and via the EVENTS/EXT CLOCK input the time base can be started after a preselected number of trigger events and the horizontal deflection speed can be controlled via the CLOCK signals (in EXT CLOCK mode) applied to this input.

8.31.2 Circuit Description of the EXT TRIG input (see figure 8.31.2.)

The control signals for this unit are coming from the management unit A25.
The EXT TRIG input unit is similar to the vertical attenuator unit except that there are only two different attenuator positions, x0,2 (:5) and x0,02 (:50). Consequently, the EXT TRIG and EVENTS/EXT CLOCK input socket is coupled to two h.f. paths and one l.f. path. Alternatively, a LINE input signal can be switched via FET V4739 to provide triggering.

The two h.f. paths have no input switching reed relay contacts.
The x0,2 attenuator consists of the capacitive-network C4701, R4701, R4702, C4702 in the gate circuit of FET V4701. A logic low control signal ETTR/5 on the base of V4728 causes this transistor to conduct, which turns on source-follower FET V4701.
In turn, V4703 conducts and the signal is passed via switching diode V4704 to the summation amplifier V4709, V4711.
The logic low control signal is also applied to a switching network, V4719, V4721, V4722, which provides the collector load via diode V4727 for V4709 in the x0,2 position. The x0,2 gain adjust is R4751.

The x0,02 attenuator consists of a double capacitive-network C4707, R4708, R4709, C4708, and R4711, C4709, R4712, C4711 in the gate circuit of FET V4706. The control and switching circuits (V4731, V4726, V4724, V4723) are identical to the x0,2 position section. When the x0,02 position is selected, the gain adjustment in the collector load of V4709 is R4753.

The 1.f. path is connected via resistor R4777 to the AC/DC switch K4701, which is controlled by a reed relay in the collector of transistor V4748.
The a.c. path is via C4742 and C4743 in series (two series capacitors to reduce leakage). Reversed diodes V4732, V4733 to earth provide input protection. With EXT TRIG selected, FET V4734 is off and FET V4736 is on. The 1.f. or d.c. signals are therefore fed via V4736 to pin 2 of operational amplifier N4701, together with the feedback signal from the output via R4761, R4783 and C4748 in the x0,2 position; also via R4784//R4785 and C4749 in x0,02 position as V4737 and V4738 are conducting (diode V4746 blocked by logic high from N4702/1).The output on pin 6 of the operational amplifier N4701 is applied via the base of buffer amplifier V4713 to the summation amplifier V4711/V4709. Here, the h.f. signal and 1.f. signals recombine. This recombined input signal is applied to V4717 and emitter follower V4718 which together form the low-impedance output driver stage. This driver stage feeds the TRIGGER SELECTION circuit on the vertical signal unit via a coaxial cable.

When LINE TRIG is selected, the EXT TRIG is inhibited by the LINE control signal LNTR applied to inputs 9 and 12 of operational amplifiers N4702:

- The output N4702-8 cuts off the h.f. path FETs V4701 and V4706 via switching diodes V4729. This output also switches off the 1.f. path FET V4736 via diode V4744.
  Transistor V4714 (switched on in LINE trigger mode) ensures that the circuit d.c. balance is maintained by taking over the current from the switching diodes V4704.
- The output N4702-14 switches on FET V4734 to short circuit the 1.f. signal to earth via diode V4743. Output N4702-14 also switches on FET V4739 to provide a LINE TRIG signal path via its source, V4738 and R4783 to the output. A parallel path is also provided via R4784//R4785.

The source-drain capacitance of FET V4738 (switched off in the x0,2 position) is prevented from giving cross-talk by the circuit V4742 and FET V4741. In the x0,2 position, a -14 V output on N4702-1 turns on V4742 and thus FET V4741, which clamps the drain to earth.

8.31.3 Circuit description of the EVENTS/EXT CLOCK input (see figure 8.31.3.)

The EVENTS/EXT CLOCK input unit is almost identical to the EXT TRIG input unit except that there is a trigger event level input (TREVLV) and no LINE TRIG input. There are two different attenuator positions, x0,2 and x0,02 (only the x0,2 (:5) is used). Consequently, the input socket is coupled to two h.f. paths and one 1.f. path. The two h.f. paths have no input switching with reed-relays.

The x0,2 attenuator consists of the capacitive network C4801, R4801, R4802, C4802 in the gate circuit of FET V4801.

A logic low control signal TREV/5 on the base of V4828 causes this transistor to conduct, which turns on source-follower FET V4801. In turn, V4803 conducts and the signal is passed via diode V4804 to the summation amplifier V4809, V4811.
The logic low control signal TREV/5 is also applied to a switching network, V4819, V4821, V4822, which provides the collector load via diode V4827 for V4809 in the x0,2 position. The x0,2 gain adjust is R4851. The x0,02 attenuator consists of a double capacitive network C4807, R4808, R4809, C4808, and R4811, C4809, R4812, C4811 in the gate circuit of FET V4806. The control and switching circuits (V4831, V4826, V4824, V4823) are identical to the x0,2 position. When the x0,02 position is selected, the gain adjustment in the colllector load of V4809 is then R4853.

The 1.f. path is connected via resistor R4877 to the negative input of comparator N4801-2.
Reversed diodes V4832, V4833 to earth provide input protection. The 1.f. or d.c. signals are fed to pin 2 of operational amplifier N4801, together with the trigger event level signal (TREVLV) coming from the management unit A25 and together with the feedback signal from the output via R4861, R4883 and C4848 in the x0,2 position; also via R4884//R4885 and C4849 in position x0,02 as V4837 and V4838 are conducting (diode V4846 blocked by logic high from N4702-7). The output on pin 6 of the operational amplifier N4801 is applied via the base of buffer amplifier V4813 to the summation amplifier. Here, the h.f. signal and 1.f. signals recombine.

This reconstituted input signal is applied to V4817 and emitter follower V4818 which together form the low-impedance output driver stage.
The output signal EVSGIN is routed via a 50-Ohm coaxial cable to the input of the event counter on the CCD LOGIC UNIT A26.
The source-drain capacitance of FET V4838 (switched off in the x0,2 position) is prevented from giving cross-talk by the circuit V4842 and FET V4841. In the x0,2 position, a -14 V output on N4702-7 turns on V4842 and thus FET V4841, which clamps the drain to earth.

8.31.4 Signal name list

UNIT A31

Signal name	Description	Signal source	Signal destination(s)
ETSGIN	External trigger signal in	A31	A32
ETTR/5	External triggering /5	A25	-
ETTR/5Ø	External triggering /5Ø	A25	-
EVSGIN	Events signal in	A31	A32
LN	Line trigger	A20	-
LNTR	Line triggering	A25	-
TRACDC	Trigger AC or DC	A25	-
TREVLV	Trigger event level	A25	-
TREV/5	Trigger event /5	A25	-
TREV/5Ø	Trigger event /5Ø	A25	-

MAT 2612 A

Figure 8.31.2 Unit A31 - EXT TRIG INPUT - circuit diagram.

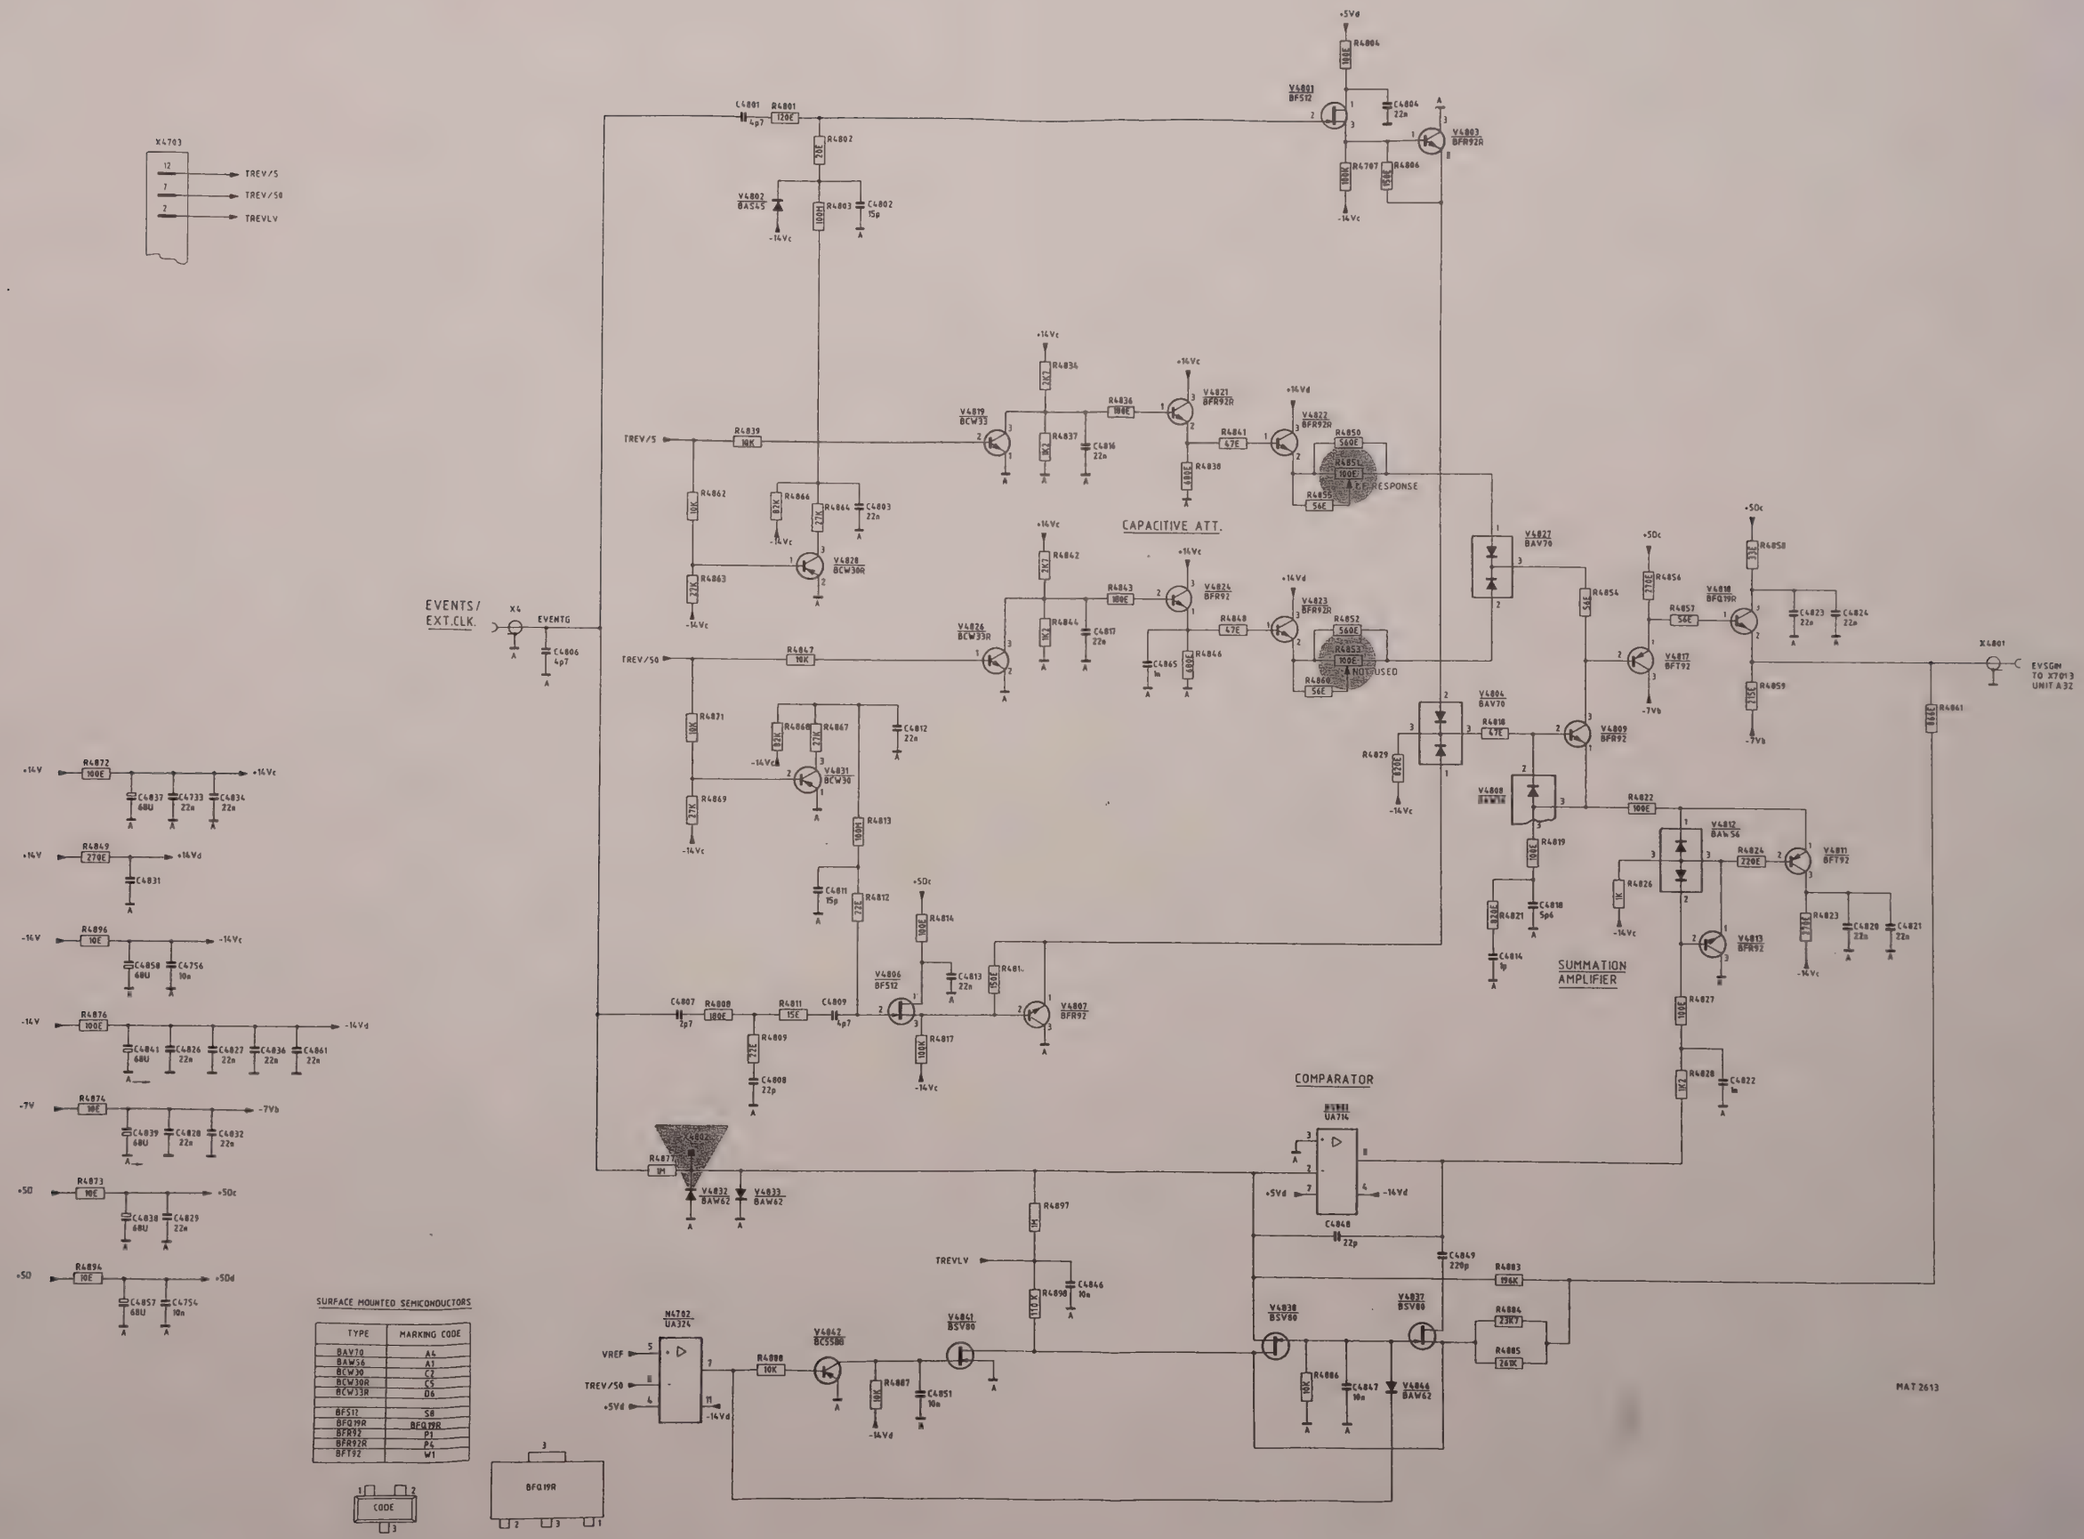

Figure 8.31.3 Unit A31 - EVENTS/EXT CLOCK INPUT - circuit diagram.

Dual trigger mode: (see also fig. 8.32.2)

The input conditions: - TRTVMO module pin 7 is high
- TRDUMO module pin 6 is high

Output D7352 pin 4 is low, so the input signal applied to the Schmitt-trigger D7351-3-6 is active on input 18 of D7352.
Output D7352 pin 6 is also low, so the input signal applied to the Schmitt-trigger D7351-17-16 that is routed via the delay line (between module pins 11 and 14) is active on input 17 of D7352 (EX-OR).
If both inputs are low or high the output pin 16 will be low. Because of the delay of 3,5 ns the pulses applied to D7352-17 are shifted in time with respect to the pulses on D7352-18.
The minimum shift is 3,5 ns. This minimum delay is necessary to compensate propagation delays.
The result is an output signal TRSG on D7352 pin 16 that is routed via module pin 9 to unit A49 module pin 2.
If the LEVEL in dual mode is turned the signal will be vertically shifted as given in the right part of fig. 8.32.2.
This vertical shift results in another pulse width of the signal TRSG. This results in other trigger level points on the signal.

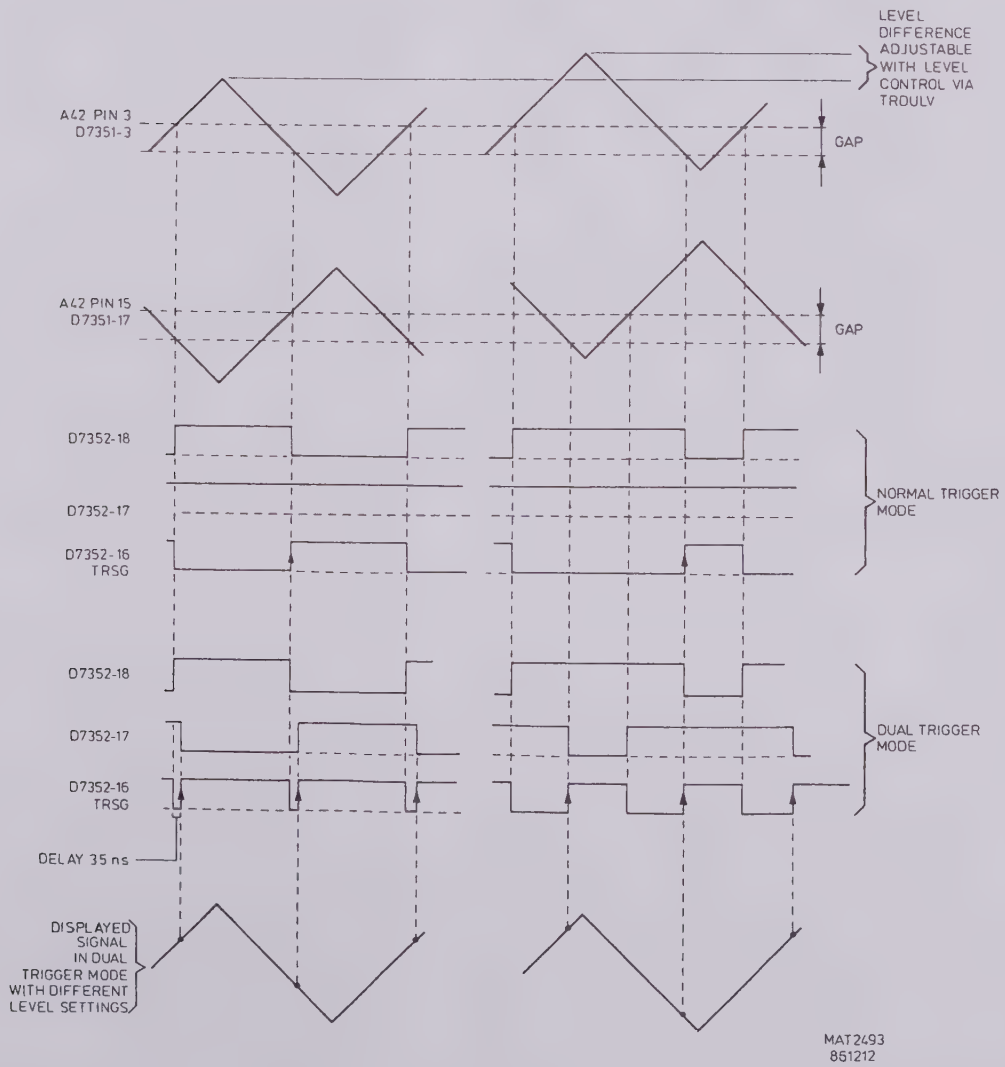

Fig. 8.32.2 Trigger logic levels

TV trigger mode:

The input conditions: - TRTVMO module pin 7 is low
- TRDUMO module pin 6 is low

In this mode the signals applied to the inputs 18 and 17 of EX-OR port D7352 are blocked, because both inputs are constantly high.
This makes output D7352 pin 16 low.
The TV sync. trigger pulse (coming from the TV sync. separator via module pin 17) are routed to module pin 9 (as TRSG) via Schmitt-trigger D7351-19-14.

8.32.8 The TV sync. separator circuit

This circuit consists of V7027...V7032 and D7003.
The input signal is derived from the TRIGGER AMPLIFIER unit A41 (module pin 22).
The trigger signal is applied via a video clipper circuit consisting of V7028/V7029 to two re-triggerable monostable one-shots in series (D7003).
These two monostable one-shots have different pulse times determined by the RC networks on pins 14 and 15 and pins 6 and 7.
The output of the first one-shot (pin 4) is applied to the clock input of D-flip flop D7004 pin 11.
This flip-flop is enabled by the TV signal.
At the output pin 9 of D7004 a 50 Hz field pulse is available.
To obtain frame pulses the inverting output D7004 pin 8 is applied to the clock input D7004 pin 3.
At the D input D7004 pin 2 the output of the second one-shot is applied.
The frame pulses now appear at the output D7004 pin 5.
The frame and field pulses are combined in the output stage V7031/V7032.
The combined field and frame pulses are fed as TV trigger pulses to the TRIGGER LOGIC unit A42 module pin 17.
To inhibit the TV trigger signals in other modes than TV mode the control signal TRTVMO is applied to the set inputs of the D-flip-flops D7004.
In TV mode this control signal is high.

8.32.7 The EVENTS AMPLIFIER unit A43 and TRIGGER LOGIC unit A42

* EVENTS AMPLIFIER unit A43

On this module the EVENTS signals coming from the EVENTS/EXT CLOCK input via A31 are converted into symmetrical signals to control the slope, the trigger symmetry and the trigger gap.
The output is a asymmetrical signal which is fed to the TRIGGER LOGIC unit A42 (module pin 1).
The integrated circuit D7401 makes the slope selection possible controlled by the signal TREVSP applied to module pin 3.
If TREVSP is high the signal path via D7401-pin 14 and 15 is open and if TREVSP is low the signal is routed via D7401 pins 16 and 17.
In this way the symmetrical signal can be inverted.
This selected signal is applied to the symmetrical amplifier consisting of four transistors in one housing D7402.
The input currents applied to the bases of D7402 pins 4 and 15 are in antiphase and are applied to the output via transistor V7401 and V7402 to the asymmetrical output. The function of V7401 and V7402 is to adapt the output level.
The currents coming out of the collectors of V7401 and V7402 are fed to the circuit V7403/V7404 and are substracted in this circuit.
The result is that the common current components are eliminated and only the current variations (signal) are fed to the output module pin 8.
On output module pin 8 a resistor divider network adjustable with R7159 is present. The function of this R7159 is to adjust the voltage output level of the EVENTS signals. This voltage EVENTS signal is fed to pin 1 of A42.

* TRIGGER LOGIC unit A42

This unit consists of logic circuits and Schmitt-trigger circuits to control the various trigger modes.
The symmetrical input trigger signals coming from the TRIGGER AMPLIFIER A41 are applied to module pins 15 and 3.
The control signals TRTVMO (pin 7) and TRDUMO (pin 6) are selecting the trigger signals for respectively the TV mode and the DUAL TRIGGER mode.
The TV sync. trigger is applied to module pin 17.

The EVENTS signals coming from the EVENTS AMPLIFIER unit A43 are applied to module pin 1.
These EVENTS signals are fed via a Schmitt trigger circuit D7351 pins 23-24-11-12 to output module pin 13.
The signal EVSG-HE is routed to the EVENTS COUNTER on the CCD LOGIC unit A26.

The selectable trigger modes are now separately described.

Normal trigger mode: (see also fig. 8.32.2)

The input conditions: - TRTVMO module pin 7 is high
- TRDUMO module pin 6 is low

The input signal applied to module pin 3 is routed via Schmitt-trigger D7351 pins 3 and 6 to EX-OR port D7352 pin 18. Input D7352 pin 17 is high in this mode (via EX-OR D7352 pin 6). The output D7352 pin 16 is as indicated in fig. 8.32.2 (the inverted signal of input pin 18).
If the level is changed (right part of fig. 8.32.2) the pulse width of TRSG will be influenced. This output signal TRSG is fed via module pin 9 to unit A49 (pin 2) for aliasing detection and start acquisition.

8.32.6 The Auto Offset Level Detection circuit.

In this circuit the peak-peak detection for the level range and the auto offset detection is done.
The input trigger signal for this circuit is derived from the TRIGGER AMPLIFIER unit A41.
The current sources V7018 and V7019 feed the input stage V7012/V7013.
To make the current sources V7018 and V7019 equal a comparator N7001 is present inbetween.
Integrated circuit D7002 (OQ 0128) is a peak detector circuit which detects, if AUTO TRIG is selected, the amplitude of the trigger signal.
If AC or DC triggering is selected (AUTO off) the peak-peak detection is not used and the level range is not determined by the peak-peak value of the trigger signal.
Only the control signal TRLV (trigger level) applied to D7002 pin 1, coming from the LEVEL control via the management unit A25 is determining the dc level of the trigger signal.
The trigger signal is shifted by control signal TRLV on D7002-1: a control range of 0 V...5 V gives a level shift range of -10...+10 div. (full level range).
If AUTO triggering is selected the control signal AULV applied to D7002 pin 13 is high and the peak-peak detector is active.
The dc level of the trigger signal is now determined by the control signal TRLV and the peak-peak value of the trigger signal. The AUTO TRIGGER LEVEL can be adjusted with R7044 via D7002 pin 5.
If AUTO OFFSET is active, the control signal AULV is high and TRLV is fixed on +2,5 V.
The dc level of the trigger signal is now only determined by its own dc component.
This dc component is fed via comparator N7003 pin 7 and 8 to the management unit A25 as control signal AOLD (Auto Offset Level Detection).
The level of AOLD can be adjusted with R7052

The uP reads this signal AOLD and adapts the dc offset in the attenuator.
After that, the signal AOLD is read again and the dc offset is corrected again etc.. up to the moment that AOLD has a correct value.
Repeating the correction sequence is necessary because the range of the ADC is ±10 div. and the offset range on screen is ± 100 div.
If the auto d.c. offset is correct, the signal AULV will become low again and TRLV stays on 2,5 V level.
In AUTO OFFSET mode, the SHIFT is set to the middle of the screen (0 V). The minimum reaction time of the OQ 0128 circuit (D7002) is 0,1 sec., so the AUTO OFFSET will not function correctly for signals with a lower repetition time.
The dc shifted trigger signals are fed to the symmetrical output stage V7023/V7024 where the TRIGGER SYMmetry can be adjusted with R7129 which is connected between the collectors of V7023/V7024.
The slider of R7129 is controlled by the signals OSTRDU and AULV via inverter N7003 and V7039.
If in AUTO, AUTO OFFSET and DUAL TRIGGER mode these signals are high, the low output D7003-14 will switch on V7039 to supply the slider of R7129.
Via dual transistor V7026 the symmetrical output is fed to the TRIGGER AMPLIFIER unit A44 for level control.
In this stage the symmetry can be adjusted with R7084. The current sources for V7026 are V7021 and V7022 and they are compared by comparator N7001.

Via the symmetrical output stage V7002 the selected trigger signals are fed to module A40 pins 14 and 15.
On unit A40 they are recombined with the signals coming from D7202 pins 16 and 17.
The current sources for the output stage V7204/V7206 are V7007 and V7008.
They are compared by comparator N7001 and can be balanced by potentiometer R7036 (in AUTO trigger mode).
The slider of the AUTO-DC jump potentiometer R7036 is connected with the -14 V via transistor V7011, which on its turn is controlled by signal AULV which is high in AUTO trigger mode.
The selected triggersignal range is fed to the TRIGGER AMPLIFIER unit A41 via V7204/V7206.

* TRIGGER AMPLIFIER unit A41

The symmetrical trigger signals are applied to module pins 4 and 12 and fed to D7251 pins 2 and 9.
The trigger signals are picked off via D7251 pins 1 and 10 and fed to the AUTO OFFSET LEVEL DETECTION circuit D7002 and accosiated circuitry.
The output signal of this circuit is fed back to the input of the TRIGGER AMPLIFIER D7251 pins 5 and 6 (module A41 pins 7 and 9) for AUTO LEVEL control.
The dc levels coming from the AUTO OFFSET LEVEL DETECTION circuit are controlling the level of the input trigger signal applied to D7251.
In D7251 the trigger slope can be selected by means of control signal TRSP. The output signal can be routed via output D7251 pins 16 and 17 (negative slope; TRSP--LX is low) or 14 and 15 (positive slope; TRSP--LX is high) to the inputs of the dual trigger circuits.
The current triggersignals are applied to the bases of transistorpairs D7252 and D7253.
On the bases of these transistors also DC levels are applied coming from the dual transistor V7034.
The positive level is applied to D7252 and the negative level to D7253.
In this way both levels are determined in dual trigger mode.
The positive and negative levels are both activated by control signal TRDUMO applied to the base of V7038 which activates current source V7037.
This current source drives the dual transistor V7034.
One base of the double transistor V7034 is connected to the positive input of comparator N7003 via a voltage divider network with potentiometer R7116 which determines the trigger gap between positive and negative triggering.
The other base of V7034 is connected with the output of comparator N7003 via which the level in dual trigger mode is determined.
Transistors V7251 and V7252 together with V7253 convert the symmetrical positive slope trigger signal into an asymmetrical voltage signal which is fed to the TRIGGER LOGIC via module pin 24.
The same is done for the other half of the circuitry by V7257/V7258 and V7259 via module pin 18.
The trigger signal used for the TV SYNC SEPARATOR is derived from V7252 via V7254 and is routed to this circuit via module pin 22.

LF filter and DC selection (D7001)

The trigger signal from the summation amplifier V7201/V7202 is also fed to D7001 pins 5 and 6.
In D7001 three symmetrical signal paths can be selected by two control signals ACTRCOHX and DCTRCOHX applied to respectively D7001 pins 10 and 9.
In fig. 8.32.1 is indicated which filter is selected with these control signals.
When DC is selected the trigger signal is routed via the outputs D7001 pins 18 and 11, when AC is selected via D7001 pins 17 and 12 via capacitors C7002 and C7003.
The trigger signals are blocked when the control signal HFTRCOHX is high and DCTRCOHX and ACTRCOHX are low and then the outputs D7001 pins 16 and 13 are short circuited (see fig. 8.32.1).
These control signals are coming from three level adapters N7002 pins 8, 14 and 7.
These three level adapters are adapting the TTL input signal to analog values: high on the input gives +7 V on the output and low on the input gives -7 V on the output

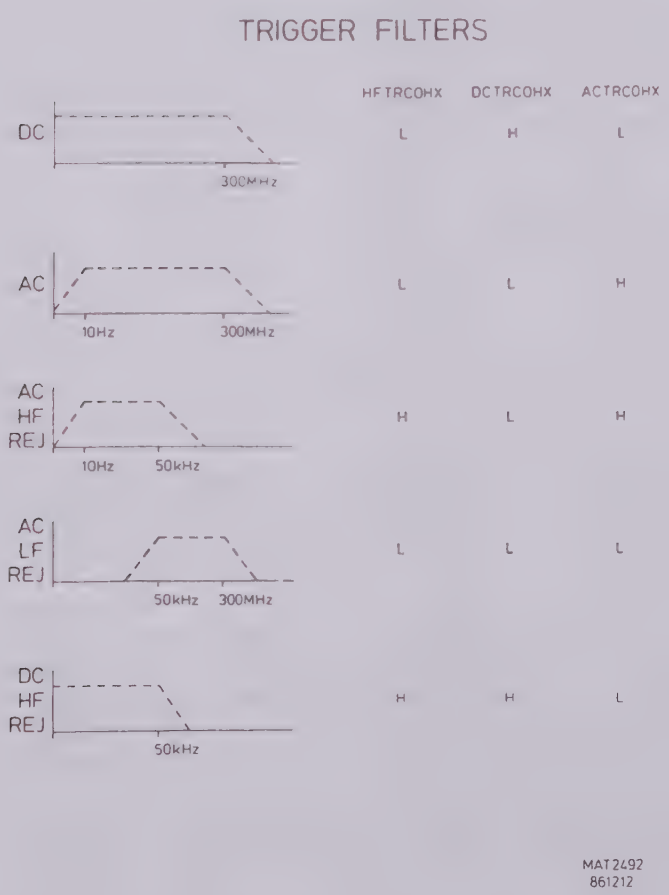

Fig. 8.32.1 Trigger Filters

8.32.4 The TRIGGER SELECTOR unit A38 (A39)

On this module A38 (A39) the trigger source channel A(B) is selected and the AC-DC balance is corrected.
The module of channel A and B is identical, so only A is described.
The symmetrical trigger pick-off signal is coming from the channel A preamplifier D5002 and is applied via module pins 2 and 5 to D5301 pins 2 and 9.
The circuitry in D5301 is symmetrical and can be balanced with potentiomter R5030 (AC-DC balance) via module pin 1.
One half of the double symmetrical output is not used and connected to the supply voltage.
The other half can be switched on and off by the control signal TRSOA- applied to module pin 7, coming from the management unit A25.
The output signal is routed to the TRIGGER FILTER unit A40.

8.32.5 The TRIGGER FILTERS and TRIGGER AMPLIFIER (units A40 and A41)

* TRIGGER FILTERS

The module A40 consists of an input circuit for the EXT TRIGGER signals (ETSGIN) and a trigger summation stage and a switch circuit for an HF filter.
The input circuit for the EXT TRIGGER signal is the same as for A and B signals on unit A38 and A39 only the input signal is asymmetrical applied to module pin 1 (coming from unit A31).
This asymmetrical input signal is converted into a symmetrical output signal, which can be selected with the control signal ETTR applied to module pin 3.
The input of the symmetrical summation stage consisting of V7201 and V7202 can be derived from channel A (module pins 5 and 21) channel B (module pins 6 and 22) or EXT TRIG (D7201 pins 14 and 15) whichever is selected.

The current sources for the transistors V7201/V7202 are V7003 and V7004 applied via module pins 8 and 9.
Both current sources are compared with comparator N7001. The balance of the current sources for AC-DC jump correction can be adjusted with R7022 connected between the collectors of V7003 and V7004.
The output of V7201/ V7202 is split up into two pathes:

- via module pins 17 and 18 to D7001 pins 5 and 6 on unit A32 for AC/DC filter selection and to input pins 5 and 6 of D7202 for HF filter selection

  HF filter selection (D7202)

  Integrated circuit D7202 selects one of the two signal pathes control by signal HFTRCOHX.
  When this control signal is high the HF filter formed by C7212, R7246 and R7247 is switched into the signal path via output pins 14 and 15 (HF REJ on).
  The HF REJ jump can be adjusted with R7019 via module pin 19.
  When sigal HFTRCOHX is low the HF filter is switched off and the full trigger bandwidth is available (see fig. 8.32.1).
  Via the output stage V7204/V7206, where it is combined with the trigger signals coming from D7001, the trigger signal is fed to the TRIGGER AMPLIFIER.

UNIT A32 - VERTICAL SIGNAL UNIT

When level A is present this level charges capacitor C8311 by the CDCPOD signal (Clamp phase).
When level B is present the voltage difference between A and B is present at the node C8311 and buffer V8312, because capacitor C8311 is clamped at level A.
This voltage is integrated during a constant time by the CDIGOD signal, when reset (CDRSOD) is low (Integrate phase). During this phase there are no switching signals to avoid interference.
Depending on the mode, one of the potentiometers R8421...R8424 (GAIN) is used to adjust the gain of the integrator. The potentiometers are connected to a reference voltage (RVCDG) to compensate offset in the P^2CCD output voltage.
Potentiometer R8319 (ZERO CORR) is used to adjust the output signal of the integrator to zero during a zero voltage sweep.
When the integration has stopped the output voltage of opamp N8311 represents the value of the sample.
This voltage remains there (Hold phase) until the reset signal (CDRSOD) becomes active. Meanwhile capacitor C8311 is clamped for the next sample.

The sequence Clamp, Integrate and Hold is called the microcycle. This microcycle is the same for all modes.
By varying the Hold time in different modes it is possible to apply the samples long enough to the P^2CCD switch to be switched through.
The samples are also applied to the differential stages. The differential stages are built up around opamps N8401 and N8411. Their outputs also go to the P^2CCD channel switch.
The P^2CCD channel switch is a multiplexer which switches the samples in the right sequence, depending on the mode, to the T&H and ADC on unit A11 (THINAN). The multiplexer is controlled by the P^2CCD output logic.

The P^2CCD control logic is built up around two PALs (Programmable Array Logic) D8303 and D8307.
PAL D8303 is driven by a number of P^2CCD status signals (CDRD-2 and CDOCØ1...CDOCØ2) coming from the management unit A25. It is clocked by CKCDOC-1, which is a 16 MHz clock signal, that is derived from the microprocessor clock on MRAM unit A5.
CKCDOC-1 also clocks latch D8301, which latches various signals from the slow clock divider, a transport clock (TCEV-LT), a sample clock (SCEV-2HT) and this sample clock divided by two by IC D8302.
The output signals control the P^2CCD channel switch, PAL D8307 and the output stages of the P^2CCDs (RSOD--LT and RSEV--LT).
The channel min/max pointer for the channel switch (CHMMPT) is derived from the MM signal (min/max) from the microprocessor and an output signal of the PAL (pin 19).
PAL 8307 is also clocked by the 16 MHz CKCDOC-1 signal. It generates a CLR signal for counter D8304, which also controls the PAL.
Furtheron the PAL generates the control signals for the CIH circuits (microcycle) and the STCV signal (Start Conversion) for the ADC on unit A11.

Resumed: a great deal of the signal acquisition in the various modes is determined by the two PALs D8303 and D8307.

8.33.6 P²CCD output circuit description

The P²CCD output circuit consists of 4 Clamp, Integrate and Hold (CIH) stages, 2 differential stages, the P²CCD channel switch, a slow clock divider and the P²CCD output logic. Figure 8.33.13 shows the principle and the timing diagram of the CIH AO circuit.

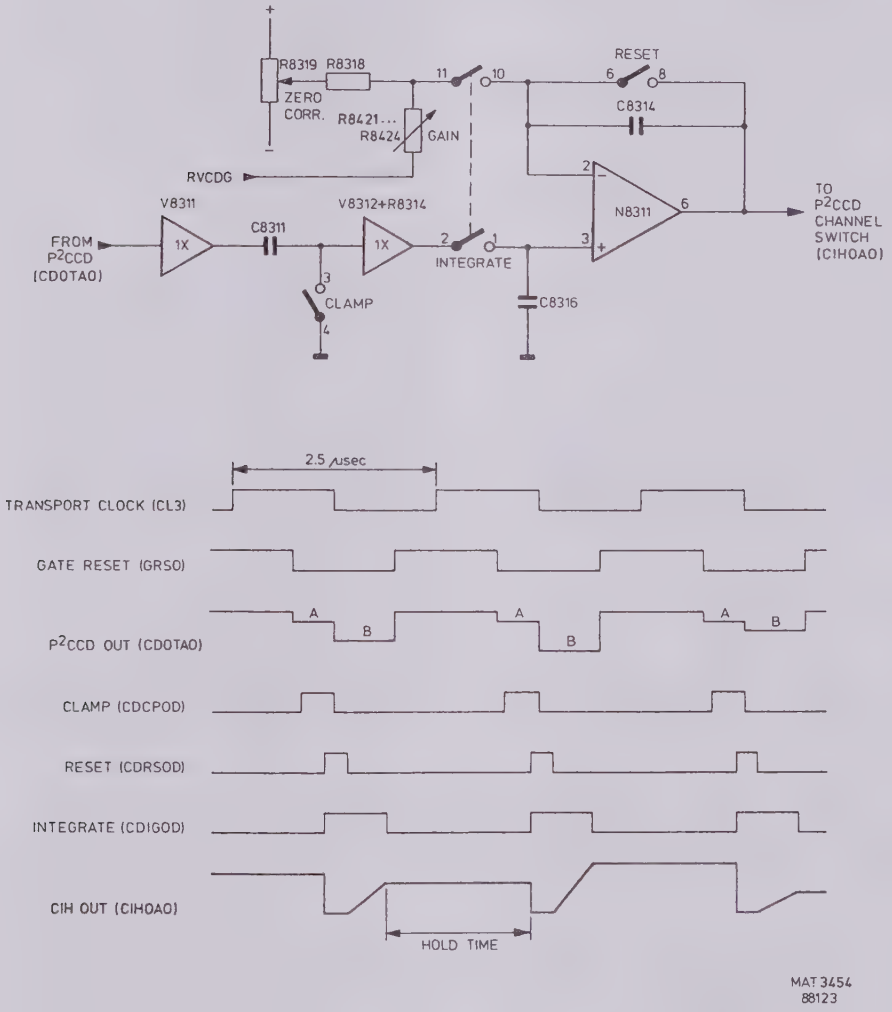

Figure 8.33.13 Principle and timing diagram of the CIH AO circuit.

While the output gate of the P²CCD is reset by GRSO its output voltage is about 20 V. This voltage is determined by the RC network at the DRSO and DRSE inputs of the P²CCD.
When this reset is removed the output voltage drops to an undefined level A. On the falling edge of the transport clock the sample leaves the output stage of the P²CCD (see also fig. 8.33.2). Now the output voltage drops to a level B. The voltage difference between level A and level B represents the value of the sample. This difference is detected as follows.

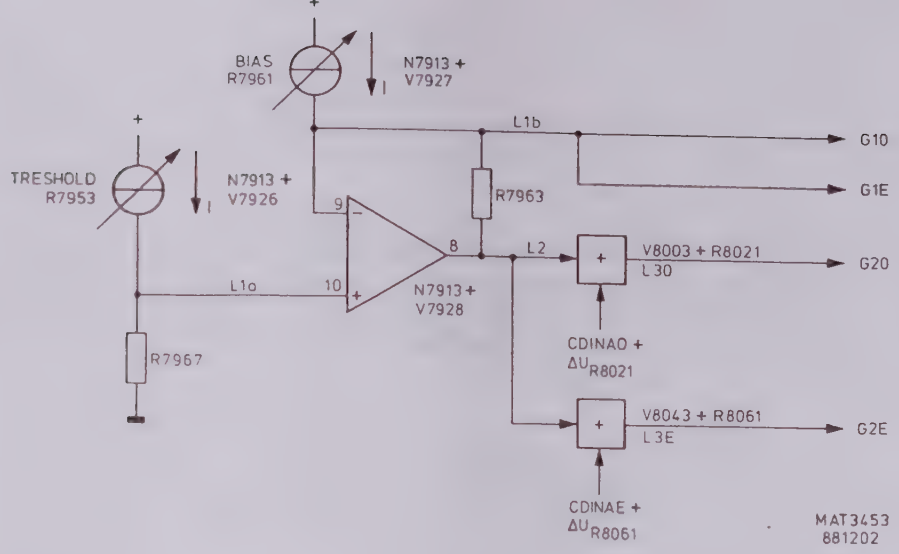

Figure 8.33.12 Principle of sample gate control.

Resumed: the circuit gives an adjustable voltage (TRESHOLD) to the G1O and G1E inputs. There is an adjustable voltage difference (BIAS) between the voltage of G1O (and G1E) and the average voltage of G2O (and the G2E).
The circuit causes the arise of charge packets in the P^2CCD. The size of these charge packets is modulated by the voltage on the G2O input (the analogue signal). These charge packets represent the samples of the input signal. Next they are transported through the P^2CCD under control of the Transport Clock.

The transport clocks (TCODA-LX) and (TCODDALX), which come from the driver unit A24, are applied directly to the P^2CCDs.
Since the transport clock on the Even side is always in antiphase with the transport clock on the Odd side, TCODA-LX is in antiphase with TCEVA-LX. TCODDALX is delayed 1 ns to TCODA-LX and TCEVDALX is delayed 1 ns to TCEVA-LX.
This results in a four phase clock system which is used for the peristaltic transport of samples inside the P^2CCD.
The output signal of the P^2CCD (OUTO = Out Odd) is led to the CIH AO circuit via transistor V8318 (CDOTAO).
Via transistor V8004 the output gate of the P^2CCD can be reset.

The remaining connections of the P^2CCD are kept at certain levels by means of simple RC networks.
These connections are:

- SUB Substrate
- DRSO Drain Reset Odd
- DRSE Drain Reset Even
- GSP Gate Separator
- DSFS Drain Source Followers.

8.33.5 P^2CCD circuit description

WARNING: The P^2CCD is a MOS device, which is sensitive for electrostatic discharges. It should be handled with care.

Since channel A and B are identical and of each channel the Even and the Odd side are identical, only channel A Odd side will be described.

The analogue input current from the signal switch (CDINAO) is led via a common base circuit, consisting of transistors V8002, V8003 and associated components, to the G2O input (Gate 2 Odd) of the P^2CCD.

The sample clock (SCODA-HX), which comes from the driver unit A24, is led to the following inputs of the P^2CCD:

- INO Input Odd
- G3O Gate 3 Odd
- G4O Gate 4 Odd

The signal STODA-HX is applied to the clock terminator circuit.
Via RC-networks (R7936,C7913 and R7937,C7914) the average DC levels of the odd and even sample clocks (ASODA and ASEVA) are applied to a differential amplifier, followed by an integrator. This is the circuit around opamp N7651. The output signal (SCOCA) is applied to the sample clock driver on driver unit A24.
This feedback system results in an equal average DC level of the odd and even sample clock.

The circuit around transistor V8001 is a current source, which gives a fixed current through resistor R8004 and choke L8007.
This results in a constant voltage difference between the G3O and G4O inputs.
The circuit around opamp N7911 and transistor V7919 is a very stable current source, which gives an adjustable current (R7939, BIAS CHARGE) through resistor R8003 and choke L8006. This results in a constant voltage difference between the INO and the G3O inputs.

Figure 8.33.12 gives the principle of the remaining circuit which is used for the control of the sample gate of the P^2CCD.
Via an adjustable current source (R7953, TRESHOLD) and R7967 a constant level (L1a) is made and buffered (L1b) by means of opamp N7913 and transistor V7928. This level is applied to the G1O and G1E inputs.
This level is dropped by means of an adjustable current source (R7961, BIAS) and R7963 (L2). To this level the voltage drop over R8021 (and R8061) and the analogue input signal is added and this is applied to G2O and G2E (L3O and L3E).

For timing reasons sometimes clock signals have to be delayed. This is done by using delay lines on cable spool assemblies as interconnection

NOTE: The sample clock signals are supplied from the driver unit A24 via 75 ohm coax cables, the transport clock signals are supplied via 50 ohm cables.

8.33.4 Signal switch circuit description

Since channel A and B are identical, only channel A is described

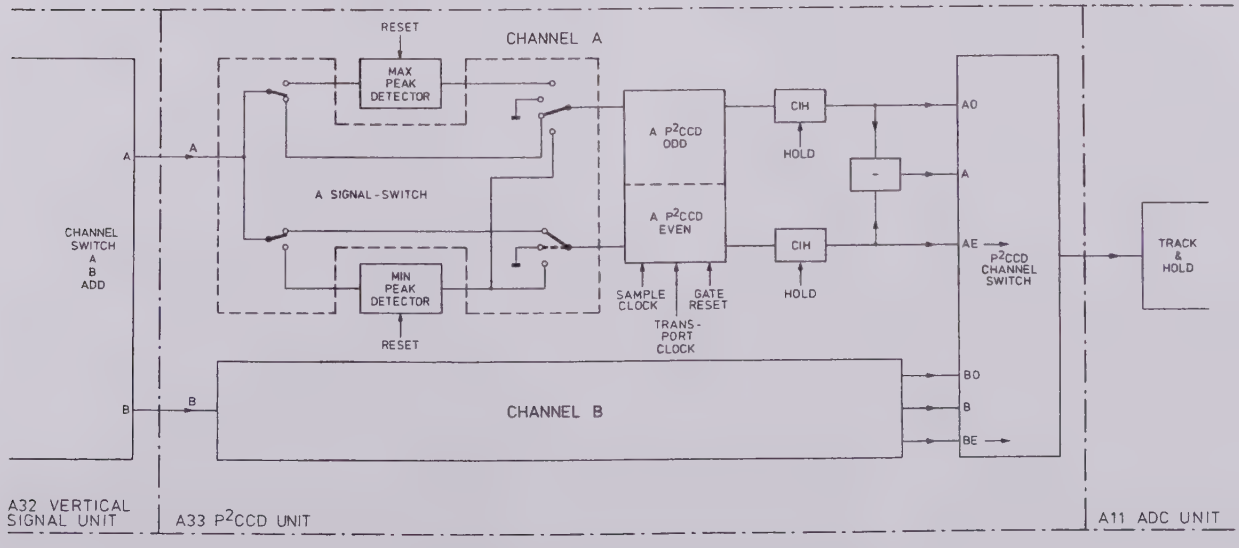
The symmetrical signals from the vertical signal unit A32 (SWINAN and SWINAP) go via V7502 and V7503 to the SIGNAL SWITCH, consisting of D7501, D5707, D5708, D5706 and associated components.
The circuit around transistors V7562 and V7563 is a compensation circuit for the DC level, when dual channel mode is switched on.
The circuit around transistor V7556 is a compensation circuit for the DC level when ADD mode is switched on. This circuit is not present in channel B.
The signal switch can guide the input signals to the MAX PEAK detector (D7502, pin 10) and the MIN PEAK detector (D7504, pin 10). The output signals of the peak detectors (pin 2) go back to the signal switch (D7507 and D7508 pin 3+4). The ICs D7507 and D7508 switch the signals to D7501 and D7506 (pins 19+20; symmetrical signal).
They can also switch a zero voltage level to pin 19 of the ICs D7501 or D7507 (pin 18, an asymmetrical signal) for the zero voltage sweeps.
Each peak detector has its own reset circuit, which is controlled by the reset pulses (RSMXPD and RSMNPB) coming from the mini CCD logic unit A49. The output currents of the signal switch (D7501 pin 22 and D7506 pin 22) go to the Odd (CDINAO) and the Even (CDINAE) side of the P^2CCD via coaxial cables.
The signal switch is controlled by 10 status signals (ST1...ST10), which are generated in the status logic. They are derived from ZECH, CHMMPT and PDSW0...PDSW2.
ZECH indicates if a zero voltage sweep is made in a P^2CCD mode or DIRECT SPECIAL mode (1 = zero voltage sweep).
CHMMPT indicates which peak detector is selected. It is generated in the P^2CCD output logic (0 = MAX, 1 = MIN).
Below the truth table for the other signals can be found.

Time base setting	PDSW 0	1	2	ST1	ST2	ST3	ST4	ST5	ST6	ST7	ST8	ST9	ST10
Normal >= 0.5 ms/div	0	1	0	1	0	0	x	x	x	x	x	x	x
Normal <= 0.2 ms/div	0	0	0	-z	-z	0	x	x	x	x	x	x	x
MIN / MAX >= 2 ms/div	1	1	0	0	1	-c	c	0	0	-c	0	1	1
MIN / MAX <= 1 ms/div	1	1	0	0	0	1	-z	0	z	-z	z	1	0

Note: z = ZECH
-z = not ZECH
c = CHMMPT
-c = not CHMMPT

8.33.3.8 RANDOM SAMPLING mode (50 ns/div...5 ns/div)
Single + Dual channel

In RANDOM SAMPLING mode samples are continously taken by the Even side of the P^2CCD with a rate of 50 MHz, so every 20 nsec. The transport clock frequency is 100 MHz, so between the samples there are dummy samples to reduce crosstalk between the samples (see figure 8.33.11). The number of samples, which are required for one sweep, depends on the time base setting.
In 50 ns/div setting, a sweep has a length of 500 nsec. The required number of samples is then 500/20=25 samples.
In 5 ns/div setting, the sweep length is 50 nsec, which means that there are 50/20=2.5 dots required.
Depending on the delta-t measurement result, 2 or 3 samples are needed. In this case there are always 3 samples taken. If the third sample is not needed, it is not used later by the DPU.
After a trigger, the sampling and transporting continues until the desired samples are just before the output gate in the P^2CCD.
Now the transport frequency changes over to 400 kHz and the samples are transported via the P^2CCD channel switch to the ADC.
In Single channel mode this switch is switched to the desired input channel (AEven or BEven).
In Dual channel this switch alternates between AEven and BEven, thereby ignoring the dummy samples (see figure 8.33.11).
When the samples are converted, a sweep of samples of zero voltage level is taken (see dashed position of signal switch in figure 8.33.11) and converted to perform digital leakage correction.
The Odd side of the P^2CCD´s is not used in this mode.
In case of a negative trigger delay (pretrigger) the P^2CCD´s serve as a pretrigger memory.
In Single channel mode, the addresses Ø, 8, 16, 24, etc of register RØ are used for samples. When the 512 different addresses are filled with samples a picture is complete. The remaining addresses are filled with interpolated samples.
In Dual channel mode the addresses Ø, 4, 8, 12, etc of register RØ are used.
In SINGLE SCAN mode, the acquisition stops as soon as 512 samples at different addresses are in register RØ.



8.33.3.7 P^2CCD mode (200 us/div...5 us/div)
Single + Dual channel, MIN / MAX

The signals from the channel switch are applied to the peak detectors. The P^2CCD´s take samples from their outputs (see figure 8.33.10). Further on, this mode works exactly equivalent as the P^2CCD mode with MIN / MAX off (time conversion principle).
In the time base setting 5 usec/div the sweep length is 50 usec. A sweep consists of 250 MAX and 250 MIN samples over 10 divisions on the screen.
So the distance between 2 MAX samples is 50/250 = 0,2 usec = 200 nsec.
The reset time of the peak detectors is 20 nsec, in which the peak detectors don´t watch the input signal.
So there is a "blind time" ratio of 10%.
In faster time base settings, the "blind time" ratio increases, so using MIN / MAX is not allowed.

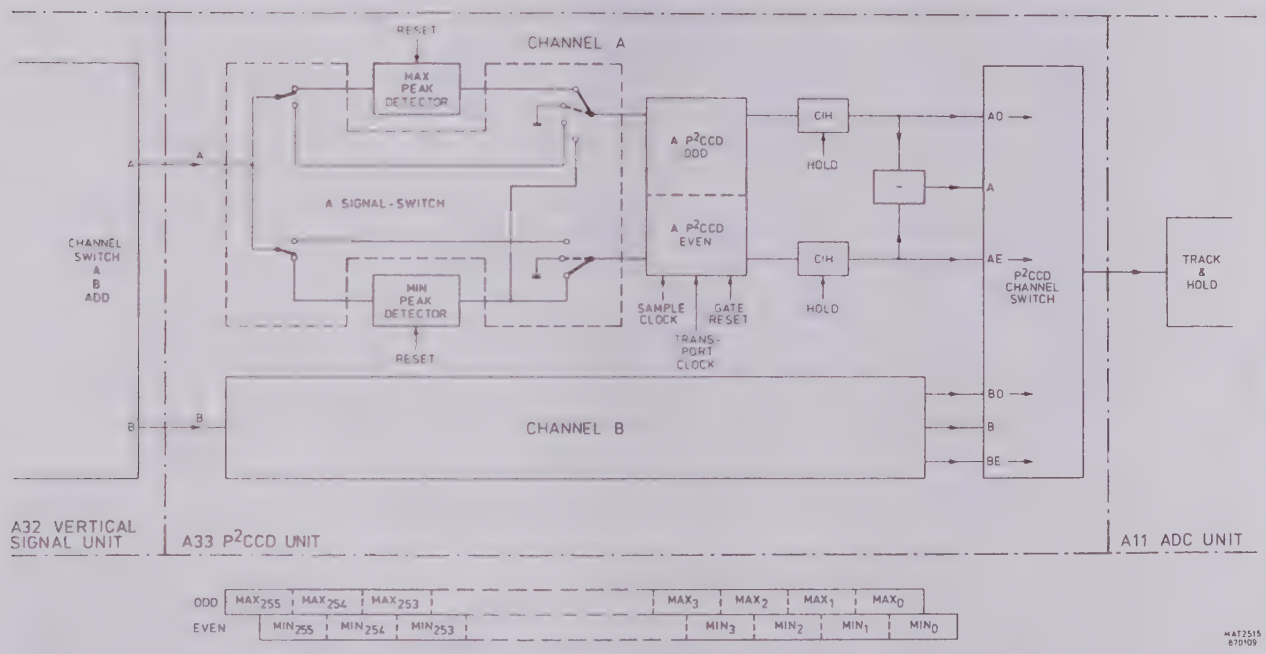


Figure 8.33.10 P^2CCD mode
Single + Dual channel, MIN / MAX.

8.33.3.6 DIRECT SPECIAL mode (1 ms/div and 500 us/div)
Single + Dual channel MIN / MAX

The signals from the channel switch are applied to the peak detectors. The Odd side of the P^2CCD takes continuously samples of the MIN peak detector, the even side takes samples of the MAX peak detector. Because the sample clock frequency (200 kHz) is the half of the transport clock frequency (400 kHz) dummy samples are placed between the MIN samples resp. the MAX samples (see figure 8.33.9).
In the 1 msec/div time base setting in Single channel mode, 4096 samples are converted after a trigger, 2048 from the MIN peak detector and 2048 from the MAX peak detector. The P^2CCD switch alternates between AO and AE, thereby ignoring the dummy samples.
Afterwards a sweep of 2x2048 samples of a zero voltage level is taken (see dashed line in figure 8.33.9) and converted to perform digital leakage correction in the DPU.
In Dual channel mode, 2048 samples (1024 on each P^2CCD side) are taken at each sweep (total 4096 samples), followed by zero sweep. The P^2CCD channel switch alternates between AO, BO, AE and BE.
In the 500 usec/div time base setting 512 samples on each channel (256 MIN samples and 256 MAX samples) are taken, followed by 2x256 zero voltage samples on each channel. The DPU performs the digital leakage correction.

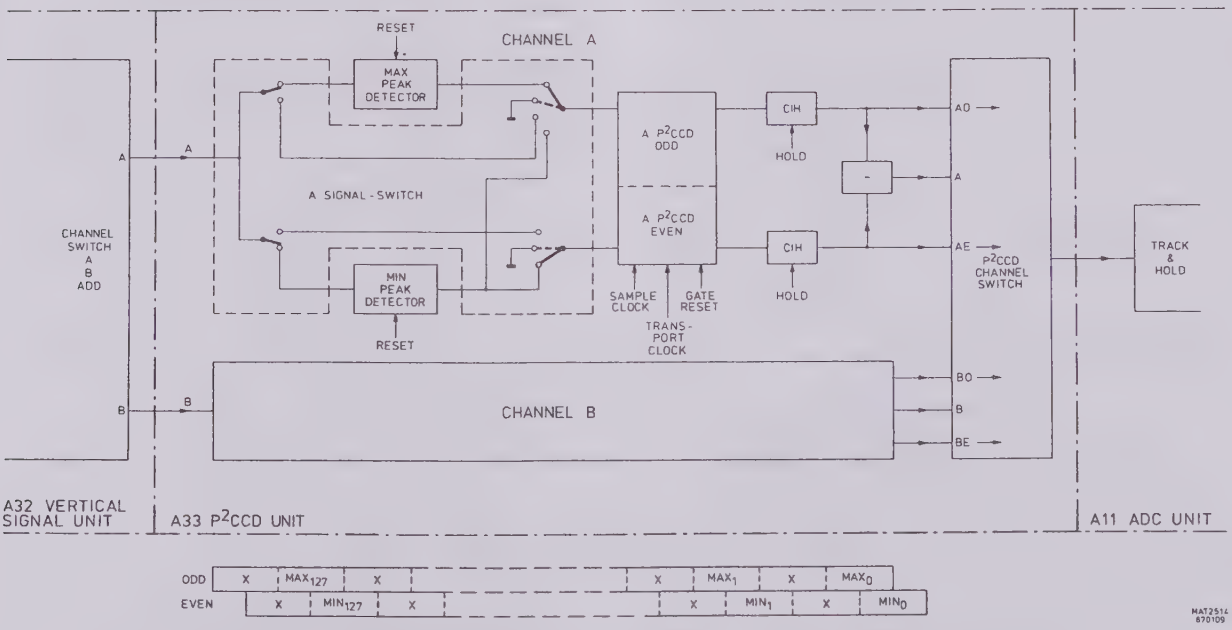

Figure 8.33.9 DIRECT SPECIAL mode
Single + Dual channel, MIN / MAX.

8.33.3.5 ROLL + DIRECT mode (360 s/div...2 ms/div)
Single + Dual channel, MIN / MAX

In these modes the signals from the channel switch are applied to the peak detectors, called resp. MAX peak detector and MIN peak detector (see figure 8.33.8).
The Odd side of the P^2CCD takes samples alternatively from the MAX and the MIN peak detector (see signal switch positions 1 and 2). Because the sample frequency is the half of the clock frequency dummy samples are placed between the MIN and MAX samples, to achieve less cross talk between the samples.

When a sample has been taken the concerning peak detector is reset with a pulse of 20 nsec. length, which comes from the CCD logic unit (A26).
The Even side of the P^2CCD takes samples of a zero voltage level, which are substracted from the Odd side samples in the differential stage behind the CIH circuits to achieve analogue leakage correction.
Next the corrected samples are selected by the P^2CCD channel swith and applied to the T&H and DAC.
In Single channel the P^2CCD channel switch remains in position A or B, depending on the selected input channel. Now every sample is converted twice, of which the DPU ignores one.

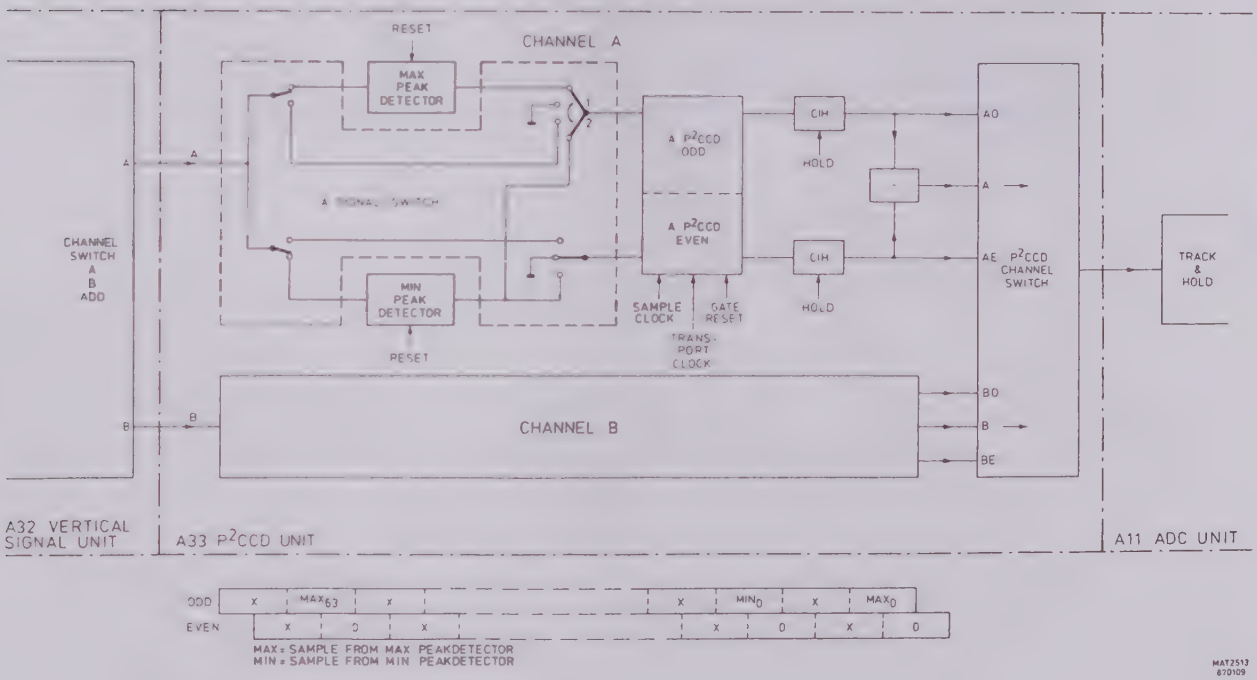

Figure 8.33.8 ROLL + DIRECT mode
Single + Dual channel, MIN / MAX.

The DPU determines which samples are placed on which address in register RØ, depending on time base settings, etc (see also ROLL + DIRECT mode, Single channel)
In the 2 ms/div time base setting in Single channel mode, all the real samples (4096/sweep) are converted.
At lower time base settings there are more samples converted as needed for placing in register RØ. Now the DPU dtermines for each series of MAX samples which one is the biggest. This sample is placed in register RØ.
The same is done for the MIN samples, but now the smallest one is placed in the register RØ.
This principle is called Digital MIN / MAX.

8.33.3.4 MAXIMUM RESOLUTION mode (500 us/div...100 ns/div) Single + Dual channel

In this mode every sweep 512 samples are taken in Single channel mode and 2 x 512 samples in Dual channel mode. The delta-t circuit on the clock unit (A34) measures the time between the trigger moment and the moment the first sample is taken. This is used to determine on which address between the first and the eight´s (4096/512) address the first sample has to be placed.
The next sample is placed 8 addresses higher and so on.
In Dual channel mode the delta-t information is used to determine on which address between the first and the fourth (2048/512) address the first sample has to be placed.
The next sample is placed 4 addresses higher and so on.

The remaining addresses are filled with samples, which are calculated by the DPU by means of interpolation.
When a new sweep of 512 samples is taken after a trigger, it is placed in the register RØ on the addresses which are determined by the value given by the delta-t circuit. So the calculated samples are replaced by real samples.
In this way, a high resolution display with low jitter is realised.
When SINGLE SCAN is selected the acquistion stops as soon as all interpolated samples are replaced by real samples.

8.33.3.3 P^2CCD mode (200 us/div...100 ns/div)
Single + Dual channel (see figure 8.33.8)

In these modes the time conversion principle is used.

Samples are taken and transported with a rate of 250 kHz to 250 MHz, depending on the selected time base setting (0,2 msec/div to 200 nsec/div.). After a trigger, the sampling and transporting is stopped after a while. The moment depends on the selected trigger delay.
The P^2CCD contains 512 samples, which are now transported with a low transport clock frequency of 100 kHz to the P^2CCD channel switch.
So every 2,5 microsecond a sample comes out of one of the P^2CCD's.
The P^2CCD channel switch alternates in Dual channel between AOdd, BOdd, AEven and BEven to apply the samples to the T&H and ADC, where they are converted (see figure 8.33.7).
In Single channel, the P^2CCD switch alternates between AOdd and AEven or BOdd and BEven, depending on the selected input channel. Now every sample is converted twice. The DPU "throws away" one of every two converted samples.
After all samples are converted, a new sweep of samples is taken with high sample and transport frequency and converted with the low transport frequency. This time the samples are taken of a zero voltage level (see dashed signal switch position in figure 8.33.8). Afterwards the DPU substracts these zero voltage samples from the corresponding signal samples to perform digital leakage correction.
The samples are placed at addressess in Register RØ in the same way as in the DIRECT SPECIAL mode.

On the screen 500 samples are displayed over 10 divisions, this is 50 samples/div. So in the time base setting 100 nsec/div every 2 nsec a sample is taken. This means a sample frequency of 500 Msamples/s, which is the maximum sample rate.
In case of a negative trigger delay (pretrigger) the P^2CCDs serve as a pretrigger memory.

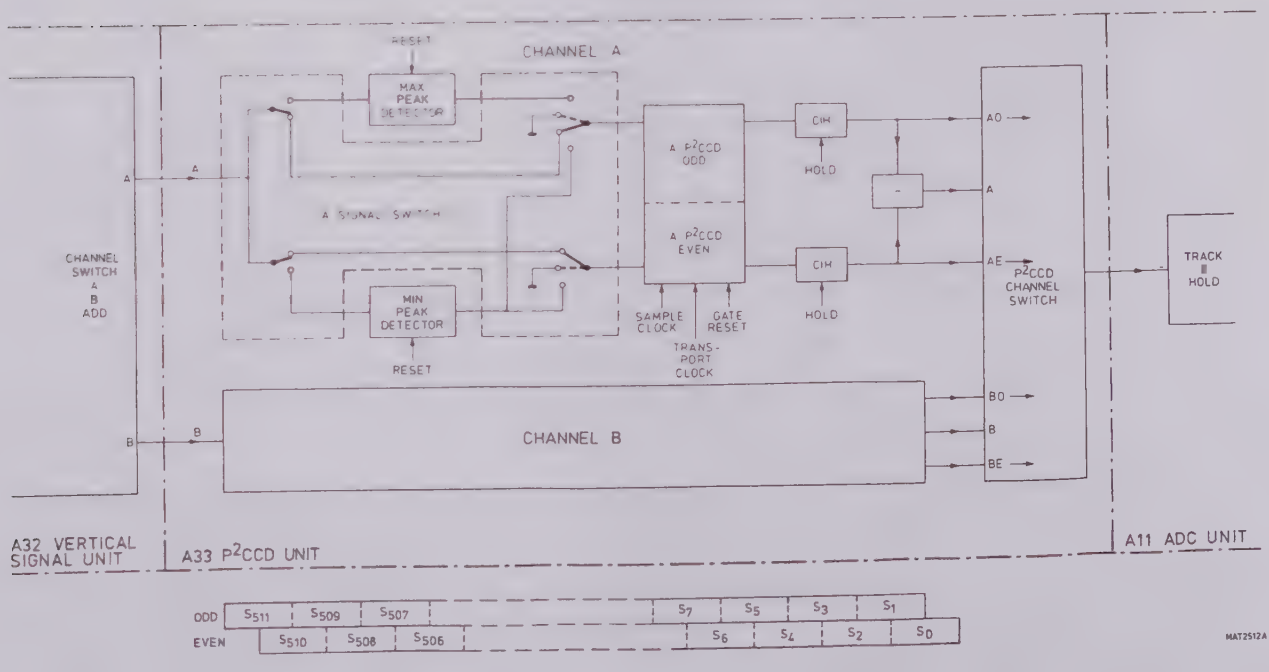

Figure 8.33.7 P^2CCD mode
Single + Dual channel.

8.33.3.2 ROLL, DIRECT and DIRECT SPECIAL mode (360 s/div...500 us/div)
Dual channel

Each channel works in the same way as described in the single channel mode (see figure 8.33.6). In both channels the samples are taken at exactly the same moments. Register RØ is now 2048 samples wide for each channel. The sample clock frequency (200 kHz) is the half of the transport frequency (400 kHz). So the real sample output rate of each P^2CCD is 200 kHz, which enables the P^2CCD switch to apply in an alternating way the samples of both channels to the T&H and ADC. The dummy samples are ignored.
In the DIRECT SPECIAL mode (500 us/div) 512 samples are taken at each channel. They are placed in addresses Ø, 4, 8, 12, etc of register RØ. The remaining addresses are filled with samples, which are calculated by the DPU by means of interpolation.

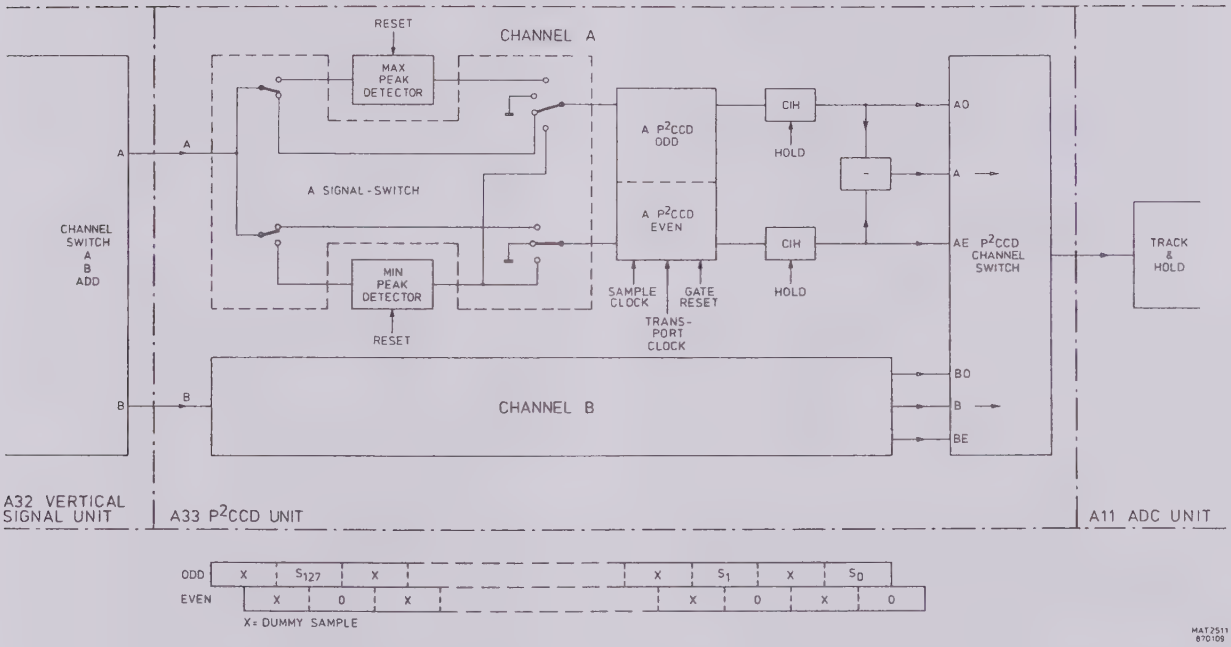

Figure 8.33.6 ROLL + DIRECT + DIRECT SPECIAL mode
Dual channel.

8.33.3.1 ROLL + DIRECT + DIRECT SPECIAL mode (360 s/div...500 us/div)
Single channel

In these modes samples are continuously taken with a rate of 400 kHz by the Odd side of the P^2CCD (see figure 8.33.5) and transported to the CIH circuit, where they can be held for a certain time. On the Even side samples of a zero voltage level are taken and transported to the CIH circuit. Signals on the Odd and Even side are substracted in the differential stage to perform analogue leakage correction of the P^2CCD circuit.
Next, the corrected samples are selected by the P^2CCD channel switch and applied to the T&H and ADC.
Every 2,5 microsecond a sample is converted.
The digital processing unit (DPU, unit A9) determines which samples are placed on which address in register RØ, depending on the selected time base setting and trigger delay.
In the 1 ms/div time base setting, all samples are placed in register RØ, which is 4096 converted samples wide.
In the DIRECT SPECIAL mode (500 us/div) 512 samples are taken. The samples are placed in addresses Ø, 8, 16, 24, etc of register RØ. The remaining addresses are filled with samples, which are calculated by the DPU by means of interpolation.

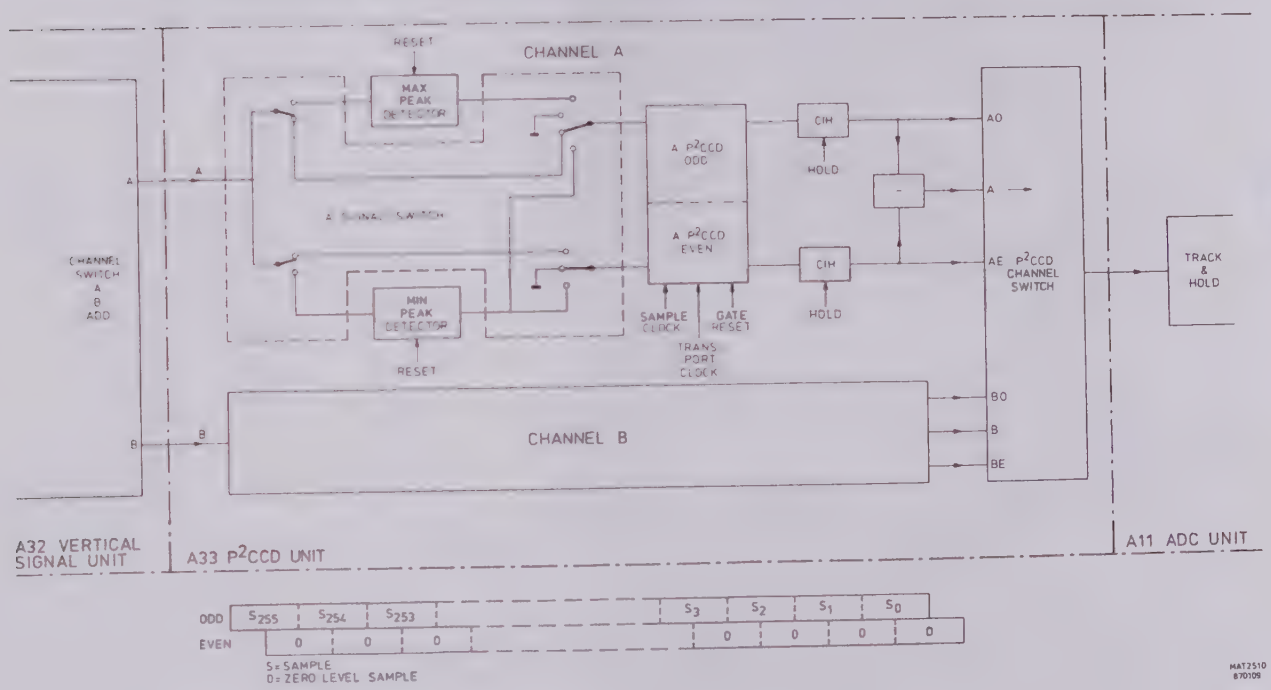

Figure 8.33.5 ROLL + DIRECT + DIRECT SPECIAL mode
Single channel.

Figure 8.33.4 shows a block diagram of unit A33. Signals from channels A and B from the vertical signal unit (A32) go via the signal switch to the P^2CCD's. The signal switch gives various switching possibilities (e.g. signals through peak detectors) for the input signals for the P^2CCD's.
Behind the P^2CCD's the already mentioned CIH circuits can be found. The output signals go directly to the P^2CCD channels switch and to a substraction stage. The substracted signal also goes to the P^2CCD channel switch.

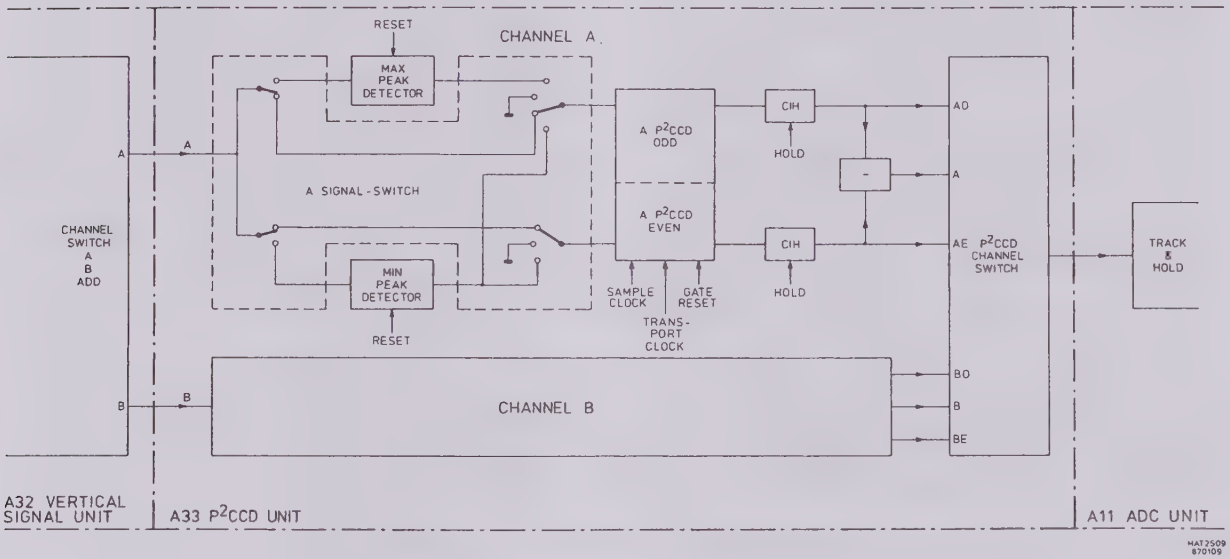

Figure 8.33.4 Block diagram of unit A33.

In all modes, the signal processing is exactly the same in both channels and happens synchronously until the P^2CCD switch. The P^2CCD switch applies the samples of both channels or one channel in the right sequence to the T&H circuit and the ADC, which can be found on unit A11.

Next all modes are discussed, illustrated with block diagrams with the signal switches in the correct position and with the schematic representation of the contents of a P^2CCD.

8.33.3 Operation of the modes

Below an overview can be found of the various modes in which the oscilloscope can operate.

	MODE				Samples/channel			
Time base Range	Normal		MIN / MAX		Normal		MIN / MAX	
	SINGLE	DUAL	SINGLE	DUAL	SINGLE	DUAL	SINGLE	DUAL
360s/div-50ms/div	ROLL	ROLL	ROLL	ROLL	4K	2K	4K	2K
5s/div-2ms/div	DIRECT	DIRECT	DIRECT	DIRECT	4K	2K	4K	2K
1ms/div			DIRECT SPECIAL	DIRECT SPECIAL			4K	2K
0,5ms/div	DIRECT SPECIAL	DIRECT SPECIAL	DIRECT SPECIAL	DIRECT SPECIAL	0,5K 4K *	0,5K 2K *	0,5K	0,5K
0,2ms/div-5us/div	P^2CCD-mode	P^2CCD-mode	P^2CCD-mode	P^2CCD-mode	0,5K 4K *	0,5K 2K *	0,5K	0,5K
2us/div-100ns/div								
50ns/div-5ns/div	RS- ** mode	RS- ** mode			0,5K	0,5K		

* Maximum Resolution
** Repetitive only

The sample clock frequency and the transport clock frequency are the same in the following modes:

- ROLL, DIRECT } Only Single channel, MIN / MAX off
- DIRECT SPECIAL} Only normal
- All P^2CCD modes, MIN / MAX off or on

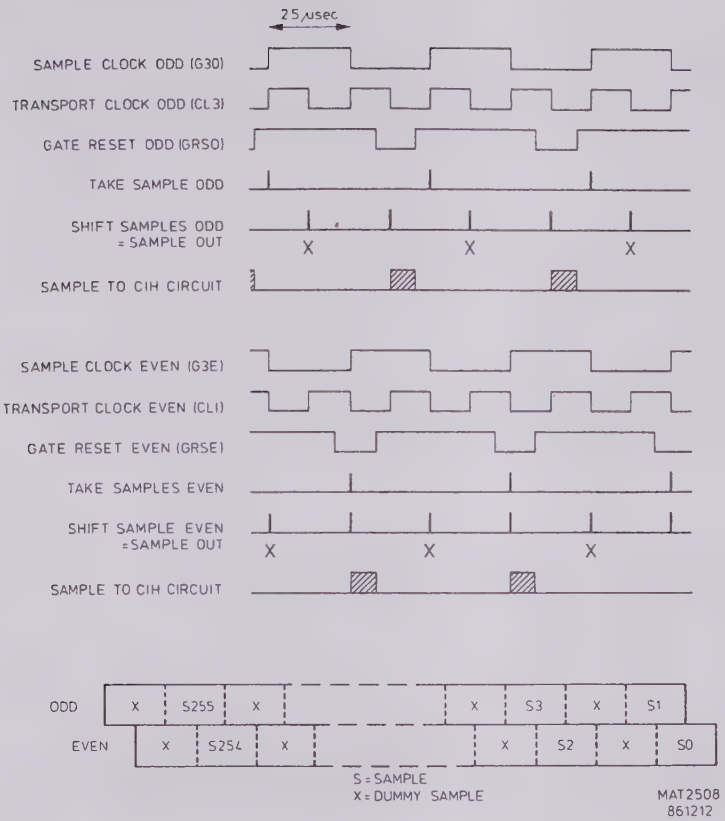

Figure 8.33.3 Sample and transport sequence II.

NOTE: The dummy samples, which are marked with an X, don´t come out the output gate, because the reset signal is active then.

During the transport, the level of the samples changes, due to leakage. This leakage depends upon the time the sample is in the P^2CCD. Of course this leakage has to be compensated. Generally this is done by taking a sample of a zero voltage level and transport it with the same speed as the original sample. As it comes out the P^2CCD its level is only determined by leakage. By substracting this level from the level of the original sample with leakage, the leakage is eliminated.

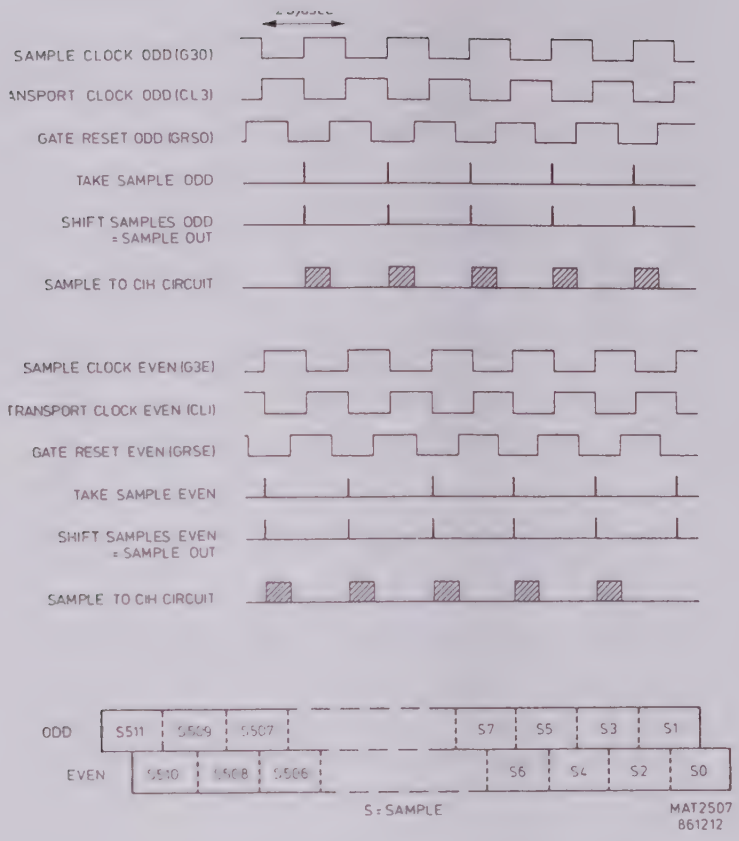

Figure 8.33.2 Sample and transport sequence I.

NOTE: The needles do not represent signals, but are moments on which a sample is taken and other samples are transported.

In some other modes the sample clock frequency is the half of the transport clock frequency. This means that transports take place, while there have no samples been taken.
In this way dummy samples are created between real samples.
These dummy samples reduce cross talk between real samples which is required in some modes.
The sampling and transport sequence and the contents of the P^2CCD are summarised below.

8.33.2 The P^2CCD description

The P^2CCD (Profiled Peristaltic Charge Coupled Device), which is basically an analogue shift register, consists of an ODD-side and an EVEN side. Each side consists of a sample gate, 256 stages through which the samples can be shifted and an output gate (see figure 8.33.1).

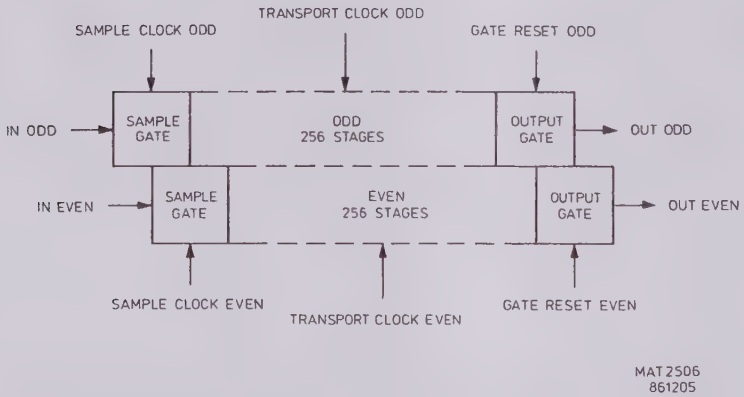

Figure 8.33.1 Schematic diagram of a P^2CCD circuit.

The clock signals of the ODD and the EVEN side are always in anti phase (see figure 8.33.2 and 8.33.3).
On the rising edge of the sample clock a sample of the input signal is taken.
On the falling edge of the sample clock this sample is shifted to the first stage. On the falling edge of the transport clock all the samples in the stages are shifted (transported) one stage and the last sample is transported to the output stage. Before the latter happens, the gate reset signal has to be removed.
Behind the P^2CCD there is a circuit that takes over the samples, after which the gate reset is applied again. This circuit, which consists of a Clamp, Integrate and Hold part, is called CIH circuit.
In a number of modes, of which an overview is given in chapter 8.33.2, the sample clock and the transport clock have the same frequency, but are in anti phase. In this case the sampling and transport sequence and the contents of the P^2CCD can be summarised as below.

8.33.1 GENERAL INFORMATION

The P^2CCD unit takes samples from the analog input signals from the Vertical Signal unit A32 and supplies these samples to the ADC and T&H unit A11. The peak detectors for the min/max function are also on this unit.

The circuits are divided over 8 diagrams:

- figure 8.33.16 signal input of both channels and status logic.
- figure 8.33.17 peak detectors and signal switch of channel A.
- figure 8.33.18 peak detectors and signal switch of channel B.

8.34.1 General information

This unit consists of two parts:

- a fast sample clock generator
- a delta-t circuit

The Mini Frequency Doubler unit A48 is also described in this section.

8

8.34.2 The fast sample clock generator

The fast sample clock generator consists of two crystal oscillators (100 MHz and 125 MHz), which can be enabled by the signals EN200MLT or EN250MLT respectively. Only one crystal oscillator operates at a time. The signal from the operating cristal oscillator (MACK) is led to the Mini Frequency Doubler unit A48. This unit doubles the frequency to 200 MHz resp. 250 MHz.

The frequency doubler operates as follows:

The input signal MACK is attenuated by the resistors R8701 and R8702. The signal amplitude is now just sufficient to make transistor V8701 conducting on the positive peaks.
The output signal of V8701 is applied to a filter, consisting of L8701, C8701 and C8702. The filter resonates at a frequency of 250 MHZ, a higher harmonic frequency of MACK.
If the 100 MHz oscillator is active, C8703 is switched parallel by transistor V8707, which brings the resonance frequency of the filter to 200 MHz.
Via a buffer stage, consisting of the circuit around FET V8702 and transistor V8703, the output signal FSCK is generated.
An amplitude detector (V8708, V8709, C8706 and R8711) detects the amplitude of the signal. The output signal of the amplitude detector is fed back to the base of transistor V8701 via opamp N8701, to stabilise the signal amplitude.
If the signal amplitude increases, the voltage on the base of V8701 will decrease. This brings V8701 less in conduction, which results in a decreasing signal amplitude.
The output signal FSCK is fed to the CCD LOGIC + FAST TIME BASE DIVIDER on the CCD LOGIC unit A26.

In the two fastest P^2CCD mode time base settings (100 and 200 ns/div) the 125 MHz crystal oscillator is enabled, which results in an FSCK of 250 MHz.
In the other P^2CCD mode time base settings (500 ns/div ... 200 us/div) and in the RANDOM SAMPLING mode time base settings (5 ns/div ... 50 ns/div), the 100 MHz crystal oscillator is enabled, which results in an FSCK of 200 MHz.
The CCD LOGIC + FAST TIME BASE DIVIDER divides this frequency down to the desired sample and transport clocks for the P^2CCDs in the various time base settings.
In all other time base settings, no crystal oscillator is enabled.

8.34.3 The delta-t circuit

The function of the delta-t circuit is to measure the time between a trigger signal and the sample clock pulse. The times that are to be measured vary from 100 ps in the Random Sampling mode to 10 us in the P^2CCD mode with Max-Resolution on. The used principle is current integration.
DAC N8511 is a serial DAC which gets its data from the microprocessor via the management unit. The data (DB15-1) are clocked in by a clock signal (CKSEDA). As soon as all bits are clocked in a latch enable clock (LDDTCK) is given, after which the data are converted.
The DAC gives an output current (Iout, pin 22), which is converted to a voltage by opamp N8512.
The output voltage (pin 6) can be adjusted by potentiometer R8602 (GAIN).
This voltage is converted to a current (DTIGCU) by opamp N8513 and associated components.
This current is led to a symmetrical circuit, which discharges (integrate) or charges (reset) capacitor C8501. In the hold phase capacitor C8501 is neither charged nor decharged.
The discharge current is determined by DTIGCU. The circuit is controlled by two signals, coming from the mini CCD logic (unit A49) on unit A26:

- a start signal (STDTSWHE and STDTSWLE)
- a stop signal (SPDTSWHE and SPDTSWLE)

The truth table is:

Phase	STDTSWHE (start)	SPDTSWHE (stop)
Reset	0	0
Integrate	1	0
Hold	1	1

x = don´t care

The voltage capacitor C8501 is buffered by FET V8506 and is led via Opamp N8502 to the input of ADC N8503.
The going low of SPDTSWLE (start of hold phase) generates a pulse via N8501 at pin 18 of the ADC. The conversion is started.
The data from the ADC (DTADDA) are clocked by a clock signal(DTADCK) into a serial parallel converter on the management unit A25.
When all data are send to the management unit, a strobe signal is

The reset level of capacitor C8501, which is a reference level, is determined by the reference output voltage of the ADC (pin 24) via opamp N8506 and the circuit around transistors D8501 and V8518.

RESUMED: The delta-t circuit is of a time measuring circuit based on integration of a current. The time range that can be measured, is determined by the amplitude of this current. The amplitude of this current is determined by the microprocessor via DAC 8511.
The measured time is calculated by the microprocessor by using the integration voltage via ADC N8503.

NOTE: If the GAIN adjustment (R8602) is not set correctly in the Random Sampling mode (5 ns...50 ns/div), then a signal on the screen shows discontinuities. These discontinuities appear every 20 ns, independent of the time base setting.
The discontinuities may be a gap (gain too low) are a vertical step (gain too high).

8.34.4 Signal name list

UNIT A34 (including MINI UNIT A48)

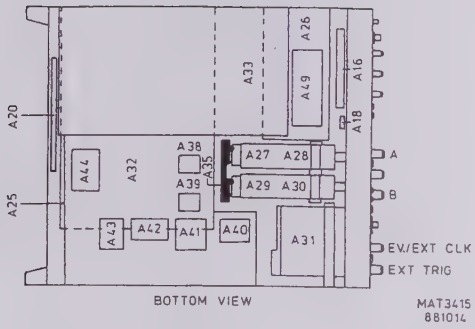
UNIT A35 - ATTENUATOR ADAPTION



CONTENTS

8.35.1 Description of the adaption unit A35..... 8.35-1
8.35.2 Signal name list..... 8.35-1

8.35.1 The adaption unit is an interconnection unit between the channel A and B attenuators (units A27...A30), the offset adaptation unit A50 and the management unit A25.
Two potentiometers R7451(A) and R7454(B) are also present to adjust the DC offset of both LF attenuators.
Also four capacitors are present to reduce interference on the probe information lines and on the 50-Ohm protection lines.

8.49.1 General

The mini CCD logic is an SMD unit, which can be found on unit A26; the CCD logic.
It consists of:

- the peak detector reset logic
- a TTL/ECL converter
- the aliasing detection circuit
- the reset auto trigger logic
- the trigger sync logic

8.49.2 Circuit description

The PEAK DETECTOR RESET LOGIC generates 20 ns reset pulses for the peak detectors on unit A33.
A reset pulse for the MIN peak detector is generated on the negative slope of D6403 pin 1. The pulse length is determined by the delay line on unit A26. A reset pulse for the MAX peak detector is generated on the negative slope of D6403 pin 19.
The reset pulses are only generated when MIN / MAX is on. In the P^2CCD mode (200 ns/div...200 us/div) the reset pulses are generated by SCEV and SCOD.
In the other modes the reset pulses are generated by RSMN and RSMX.
The generation of the reset pulses is controlled by the MMSLØ1 and MMSLØ2 signals according to the following truth table:

Time base range	MMSLØØ	MMSLØ1	Reset pulse from:
5 us/div...200 us/div	1	0	SCEV + SCOD
500 us/div...360 s/div	0	1	RSMN + RSMX
5 ns/div...360 s/div	1	1	None, MIN / MAX OFF

Gate D6401 pins 20, 12 and 13 is a TTL-ECL level converter for the SYSWTB signal.

The RESET AUTO TRIGGER circuit consists of a flip flop which is clocked by the TRSG signal. It can be enabled by the ENAURSLT signal. The output signal RSAUFF resets the AUTO TRIGGER logic on unit A26.

The ALIASING DETECTION detects if the sample frequency is lower than twice the trigger signal frequency.
The FSTB--HE signal is divided by two divide-by-two stages (D6406). The first stage can be bridged by D6409 (pins 18 and 5) under control of the DR signal via transistors V4616 and V4617.
The frequency of the signal at pin 11 of D6406 is always the sample frequency divided by four. This signal is applied to a two stage clocked circuit with D-type flip flops (D6404).
The open D input of the first stage is "Ø" (pin 6). On the first clock pulse of TRSG, the D input of the second stage (pin 15) becomes "1". On the next TRSG pulse output pin 14 becomes "1", unless the first stage is set earlier by the signal from pin 11 of D6406 via D6403 pins 24 and 12. So if the frequency of TRSG is twice or more of the quarter frequency of the sample clock then pin 14 of D6404 goes high. Due to the feedback line to pin 16 it stays high.
Then the ALID signal goes high. This is read by the microprocessor and it lights the pilot lamp on the front panel. The microprocessor also generates the RSALIDLT signal, which resets the circuit.Transistors V6401 and V6402 convert from ECL to TTL level.

In the time base range (200 us/div...5 ns/div) the DR signal is low. This resets the first stage of the divider (pin 17 of D6406) and it is bridged by D6409.
FSTB--HE is divided by two; unless flip flop D6406 is set via a set signal at pin 23.
This set signal comes from flip flop D6406 pin 8.
This flip flop is set by STAL (pin 3) and clocked back to the reset state by DTUF-2 (pin 5).
When DR is low the aliasing detection operates only between the STAL and the DTUF-2 signal, so only before the read out stroke of the P^2CCD mode.

In the time base range (360 s/div...500 us/div) the DR signal is high. Now both divider stages operate.
Because transistor V6418 conducts pin 3 of D6406 is high. The signals STAL and TDUF-2 have no influence. The FSTB--HE signal is divided by four. The aliasing detection operates continuously in the direct modes.

The TRIGGER SYNC LOGIC generates the start and stop signals for the delta-t circuit, a trigger signal for the auto trigger logic and an enable signal for the events counter and the trigger delay counter on unit A26.
When HDOF is low, a trigger signal (TRSG) sets the output of flip flop D6408 pin 14.
If it takes more than 10 usec before a trigger occurs, the flip flop is set by D6409 pin 14, due to the pulse circuit R6506...R6509 and C6417 and D6409.
The second trigger sets the flip flop in D6408 with output pins 7 and 8. Via transistors V6406...V6409, which convert from ECL to TTL level, the TRSGØ1 signals for the auto trigger logic on unit A26 are set.
When events is not selected via the ENEV--LT signal, the flip flop in D6408 with output pins 11 and 12 is also set by the second trigger. This sets the STDTSWHE and STDTSWLE signals via D6409 which start the delta-t circuit.

When events are selected, V6403 conducts. Now the STDTSW signals are not set by the second trigger, due to the high level at pin 1 of D6408. The base of V6409 is set at the ECL threshold level. Therefore the level of ENEVCNLT is determined by the level of D6408 pin 8 via V6408.
After the second triggerpulse this level goes low and ENEVCNLT goes low, which enables the events counter on unit A26 to count events.
When the events counter on unit A26 has counted down, the EVUF signal goes high. This sets STDTSWHE and STDTSWLE via D6401 and D6409.
The SPDTSWHE and SPDTSWLE signals, which stop the delta-t circuit on unit A34, are set via a two stage flip flop circuit consisting of D6407 and D6409.
In the time base range 100 us...360 s/div the DTPUSL signal is low. The stop signals are set by the first sample pulse of FSTB--HE at pin 20 of D6407. In the other time base ranges DTPUSL is high. Now the stop signals are set at the second pulse of FSTB--HE.

After the stop signals are set, the next pulse of FSTB--HE sets the outputs of flip flop D6407 pins 7 and 8. The trigger delay counter on unit A26 is enabled via ENTDCNLE.
This counter can also be enabled by the STTDCNLE signal, which is done during the zero correction stroke in the P^2CCD and the random sampling mode.

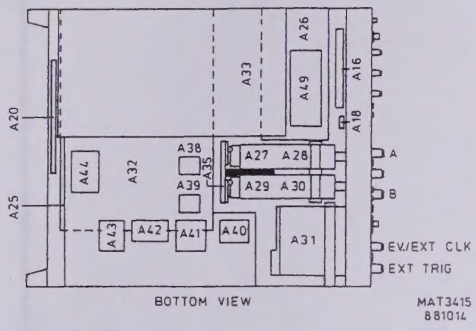
UNIT A50 - OFFSET ADAPTION UNIT



CONTENTS

8.50.1 Circuit description..... 8.50-1
8.50.2 Signal name list..... 8.50-1

8.50.1 Circuit description

The offset adaption unit, which is located between the vertical attenuators, consist of two common mode suppression circuits for the offset signals for both channels and a number of interconnections, for the control signals for the channel A attenuator.
Each suppression circuit (N7462 for channel A and N7461 for channel B) consists of an opamp circuit, which suppresses common mode interference signals on the AOSA and SOSA inputs (AOSB and SOSB for channel B). The differential signal between both inputs, which is the offset signal, is amplified one time. The output signals (OSA and OSB) are applied to the LF vertical attenuator units A28 (channel A) and A30 (channel B), via the attenuator adaption unit A35.
